of eight tests) observed at the beginning and end of twenty minute periods, the thermocouples being removed during the time of treatment. According to the results submitted, the temperature rise of the deep-lying tissues of the thigh was higher than that obtained with conventional diathermy—the criterion for evaluating short wave machines which the Council had adopted. The Council's investigator reported that the machine supplied sufficient energy to heat the body tissues whenever such treatment is indicated and gave satisfactory service for tissue cutting.

Burns may be produced by this machine but, with ordinary care, they may be avoided, it is highly probable that they will not occur and the danger is much less than with conventional diathermy.

In view of the foregoing report, the Council on Physical Therapy voted to include the Barr Ultra-Short Wave Radio-thermy Unit Model SW-5 in its list of accepted apparatus.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

- 1 LOEB'S GLUTEN FLOUR
- 2 FARWELL & RHINES CRISS CROSS BRAND GLUTEN FLOUR

Manufacturers—(1) Loeb's Dietetic Food Co., New York.
(2) Farwell & Rhines Co., Watertown, N. Y.

Description—Gluten flour prepared from wheat flour by removal of part of the starch, containing not more than 10 per cent moisture and, calculated on the water-free basis, not less than 71 per cent nitrogen nor more than 56 per cent nitrogen-free extract (the protein factor 57 being used) and not more than 44 per cent of starch (as determined by the diastase method).

Uselessness as a Special Purpose Food—These gluten flours are manufactured specially for use in diets restricted in dextrose formers. To be eligible for acceptance, such type of flour shall contain dextrose formers yielding dextrose in an amount not greater than 33 Gm. per hundred cubic centimeters (the dextrose equivalence being computed as the carbohydrate, plus 58 per cent of the protein, plus 10 per cent of the fat content of the food). Dextrose formers of these gluten flours, however, yield approximately 50 Gm of dextrose per hundred cubic centimeters.

There is authoritative evidence that commercially prepared special diabetic foods are of limited usefulness to the diabetic patient and that the availability of insulin makes them no longer necessary. Artificial substitutes for ordinary foods are not to be favored, it is much better for the diabetic patient to learn how to plan his diet with foods in common use and readily available. The diet should be exactly prescribed in carbohydrate, protein and fat, and total calories.

The designation of a food as a "diabetic food" merely because it is low in carbohydrates is now unwarranted and misleading and gives the erroneous impression either that the food taken in unrestricted quantities in diabetes is harmless or that it has remedial action. Except for the necessity of restricting foods to avoid overstepping the food tolerance, there are no special diabetic nutritional requirements. The exploitation of starch-free or low carbohydrate foods containing an excess of protein for use by diabetic patients is unwarranted. Protein may be tolerated almost as poorly, if not quite as poorly, as starch in diabetes.

Because Loeb's Gluten Flour and Farwell & Rhines Criss Cross Brand Gluten Flour are adjudged without usefulness or special adaptability for inclusion in diets restricted in dextrose formers, they will not be listed among the accepted foods of the Committee on Foods.

Gluten flours of other manufacturers, for the reasons stated are not eligible for acceptance.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

- 1 MARY'S BEST BRAND GOLDEN TABLE SYRUP
- 2 SHURFINE BRAND GOLDEN SYRUP
- 3 SHURFINE BRAND WHITE SYRUP

Distributors—1 Domanik Wholesale Grocery Company, Racine, Wis. 2 and 3 National Retailer Owned Grocers, Chicago.

Packer—D. B. Scully Syrup Company, Chicago.

Description—1 and 2 Table syrup, corn syrup flavored with refiners' syrup. The same as Banner Blue Syrup (THE JOURNAL, March 5, 1932, p. 817).

3 Table syrup, corn syrup sweetened with rock candy syrup flavored with vanilla and coumarin. The same as White Crystal Table Syrup (THE JOURNAL, April 15, 1933, p. 1174).

MELLOW BRAND MILK—HOMOGENIZED, PASTEURIZED

Distributor—Brown's Creamery Co., Detroit.

Description—Bottled, pasteurized, homogenized milk.

Preparation—Milk obtained from tuberculin tested herds, government and company inspected, is pasteurized by the holding method (61 C for thirty minutes), homogenized, cooled and bottled, by the usual procedure (THE JOURNAL, Sept. 1, 1934, p. 681).

Analysis—Standardized to contain not less than 35 per cent of milk fat.

Calories—07 per gram, 20 per ounce.

Claims of Distributor—The cream does not separate. The curd formed in the stomach is softer than that from unhomogenized milk.

RED & WHITE BRAND UNSWEETENED HAWAIIAN PINEAPPLE JUICE

Distributor—Red & White Corporation, San Francisco.

Packer—Alexander & Baldwin, Ltd., San Francisco.

Description—Canned unsweetened pineapple juice retaining in high degree the natural vitamin C content. The same as Greetings Brand Pineapple Juice (Unsweetened) (THE JOURNAL, Aug. 17, 1935, p. 513).

OUR LADY'S BRAND MUSHROOMS

BUTTONS (FANCY—FIRST CHOICE—MINIATURE)—SLICED—SLICED STEMS AND PIECES

Packer—Michigan Mushroom Co., Niles, Mich.

Description—Cooked mushrooms, whole, sliced, or sliced pieces and stems, with added water and salt the same as Excelsa Mushrooms, Fancy Buttons, Pieces and Stems, and Sliced (THE JOURNAL, Aug. 4, 1934, p. 342).

PURINA BRAND WHOLE WHEAT BREAD

Manufacturer—Frank's Hot Shops, Inc., Little Rock, Ark.

Description—A whole wheat bread made by the straight dough method (method described in THE JOURNAL, March 12, 1932, p. 889), prepared from whole wheat flour, water, powdered skim milk, sugar, hydrogenated cottonseed oil, yeast, salt malt extract and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

PHYSICIANS SPECIALIZING IN PATHOLOGY AND CLINICAL PATHOLOGY

PREPARED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The Council on Medical Education and Hospitals has maintained lists of approved clinical laboratories and physicians specializing in pathology and clinical laboratory work since 1926. The list of approved clinical laboratories was discontinued in 1931 and replaced by the list of physicians specializing in pathology and clinical pathology.

The Council has always held that the practice of pathology and clinical pathology is a part of the practice of medicine. In many states the law does not specifically prohibit the interpretation of laboratory observations by others than licensed physicians, so that laymen have entered upon this field of practice. Through the activities of non medical clinical laboratories the interests of the patient are jeopardized and frequently the true source, nature and progress of the disease are not ascertained. There is satisfactory evidence of the salutary influence of the Council on Medical Education and Hospitals in the gradual decrease in the number of lay-supervised hospital and independent clinical laboratories. Physicians everywhere have been constantly reminded of the importance of the medical laboratory and have been encouraged to patronize only such clinical laboratories as are directed by physicians listed by the Council or eligible for such recognition.

After nine years of experience with the clinical laboratory situation results, no less satisfactory than the supervision established over medical schools and hospitals, are being realized through the Council's endeavors.

The following list contains the names of 852 physicians who were found to meet the "Essentials" and were recommended by the Council's advisers. Those engaged in teaching, research and other activities are admitted, as well as those in active practice. For the list of pathologists in government service, see page 1351.

SATURDAY, OCTOBER 26, 1935

RESEARCH ON THE ELEMENTARY BODIES IN VIRUS DISEASE

Among the serious diseases that affect man and still engage the curiosity of medical research are those believed to be caused by viruses. Some of these have prevailed as world wide epidemics. Others through frequent localized outbreaks have taken the lives of countless children and left others permanently injured. Our knowledge of methods of prevention of some of the virus diseases has advanced more rapidly than the knowledge of their causes.

In 1904, Borrell observed enormous numbers of minute bodies in scrapings from the lesions of fowl-pox. Two years later, Paschen observed similar minute bodies in material from vaccinia and smallpox. Little attention was given to these observations for about twenty-five years for the simple reason that these minute bodies were thought likely to be artefacts or protein aggregates. Recently, however, intense research has been focused on the minute elementary bodies in virus diseases by numerous investigators. Like others, Ledingham¹ of the Lister Institute of London entered this field with prejudice against the importance of the elementary bodies. Finally he became satisfied that such bodies were present in suitably stained material, and he followed their variations in number and location as the virus disease progressed. In 1931 he reported that the elementary bodies of Paschen were demonstrable in large numbers on the second or third day in material from the rabbit lesion, while on subsequent days they decreased in number, with a tendency to congregate in the neighborhood of cells of the lesion, especially the polymorphonuclear cells. The next objective was to obtain these bodies from the raw material in pure suspension. With the use of ether and the centrifuge it was possible to separate sharply the epithelial and the degenerated polymorphonuclear cells from the other constituents of the raw material, leaving an opalescent fluid below. When centrifugated again this fluid yielded a deposit extremely rich in

elementary bodies. By continuing the process of fractional centrifugation, he obtained a fairly pure suspension of Paschen elementary bodies. Then it was shown that an animal injected with a single dose of virus intradermally developed, about the fifth or sixth day, agglutinins in the blood serum, which rose to a maximum and then slowly declined, exactly as agglutinins do in response to a dose of bacteria.

When pure suspensions of elementary bodies are wanted for infectivity tests on animals, a somewhat different technique must be followed to avoid contact with ether. Instead, the raw virus-containing material from the lesion is roughly centrifugated, then filtered through a Berkefeld V filter, and the filtrate centrifugated at high speed (15,000 revolutions per minute) for at least half an hour. The great mass of elementary bodies will thus be thrown down. With this technique, Ledingham and his associates obtained suspensions of the elementary bodies in vaccinia and carried out infection experiments. They showed that a powerfully infective vaccinia filtrate could be completely depleted of its infective power by means of the high speed centrifuge, furthermore, that the deposit of elementary bodies thrown down by the centrifuge alone proved to be infective. These experiments have been repeated and confirmed by other investigators. The conclusion seems warranted that the elementary bodies are almost surely the virus agents of vaccinia.

This method of experimentation has been applied in research on variola, varicella and herpes zoster, and probably it will be extended to more of the virus diseases. Amies, a colleague of Ledingham, has conducted serologic tests with the elementary bodies. The material from variola minor was inoculated into the skin of the monkey, and a suspension of the elementary bodies from the lesion was prepared, a suspension was prepared also from the dermal reaction in the rabbit in response to variola virus. It was found that the serums of animals experimentally infected with variola minor produced little or no agglutination of the elementary bodies prepared from vaccinia lesions, whereas in a high proportion of the experiments these serums agglutinated the elementary bodies obtained from variola material. Singularly, monkeys infected with variola developed agglutinins for the elementary bodies of variola but not for vaccinia, whereas rabbits inoculated with material from these monkeys developed agglutinins both for variola and for vaccinia. Some common antigen, therefore, is shared by variola and vaccinia. The precise change that takes place in the antigen when variola assumes by passage the attenuated form of vaccinia, however, must be left to future research by means of absorption experiments.

Amies also studied the elementary bodies in varicella. Fluid from the earliest vesicles was placed in a citrated saline solution and cleared by centrifugation at low speed, the supernatant fluid was then centrifuged

¹ Ledingham J. C. G. Studies on Virus Problems. Bull. Johns Hopkins Hosp. 57: 32 (July) 1935.

gated at high speed and the elementary bodies thrown down. To get sufficient elementary bodies many vesicles had to be pricked, as only those which gave clear fluid could be used. Since in varicella the agglutinins that appear about five days after the onset of the eruption persist for some time, it may be possible by means of agglutination tests with suspensions of varicella and variola elementary bodies to decide doubtful cases of smallpox when varicella is suspected.

Some intimate connection between varicella and herpes zoster has been indicated for years by clinical and epidemiologic evidence. It is not unusual for varicella to occur among contacts of a case of zoster, and there appear to be authentic records of zoster following exposure to varicella. By the foregoing methods of isolation of elementary bodies and the agglutination test, Ames obtained agglutination of the corresponding elementary bodies in all but two of thirty-two cases of herpes zoster, while in nineteen of them the serums also agglutinated varicella elementary bodies.

Since similar results have been secured by others, there is at last some agreement that many viruses are represented by visible and workable elementary bodies. There lies ahead the goal to add much more knowledge of the behavior of each virus in the host and, if possible, its cultivation in more artificial conditions outside the host. The present available knowledge of viruses is indeed limited. At the moment, for example, where do we stand on the most crucial question, Are these viruses really independent living agents?

TRAUMATIC SHOCK

A large volume of literature has accumulated on the subject of traumatic shock¹ and numerous theories concerning its etiology have been advanced. The obvious picture of prime importance among the phenomena attending shock is the low arterial pressure, two theories for the explanation of this condition have generally received the most attention. One suggests a traumatic toxemia, with the absorption of metabolic toxins from the traumatized areas, followed by a secondary generalized vasodilatation and augmented permeability of the capillaries. The other hypothesis that has been emphasized supports the contention that the condition of shock is caused by the local loss of blood and/or plasma, resulting in a marked decrease in the volume of circulating blood. Hemorrhage is the simplest and most direct method of reducing blood volume, and the similarities between traumatic shock and the results of serious hemorrhage have led observers to remark that the conditions of hemorrhage and shock are identical. This statement is in agreement with the evidence now available. In addition to the factors mentioned in the production of traumatic shock, it seems highly probable that certain nervous influences are of importance. There is the possible

inhibition of vasoconstrictors and stimulation of vasodilators in acute circulatory collapse and, what is even more likely, a prolonged activity of the sympathetic system when circumstances arise which bring that system into operation.²

Although the evidence supporting the circulatory theory of traumatic shock is in general in good agreement, much confusion exists with respect to efforts designed to support the "toxic theory" of the etiology of traumatic shock. The carefully controlled work of Cannon and Bayliss³ produced data which suggest that a toxic factor is of importance in shock experimentally induced in cats. However, there is considerable evidence against the theory of traumatic toxemia.² The evaluation of the experimental results is made quite difficult because they have been obtained with a variety of animal species and with the use of many diverse methods for the preparation of extracts containing the blood volume-reducing toxic factor. In fact, it is possible to produce from a wide variety of normal tissues extracts which contain both pressor and depressor substances.⁴ There has been a lack of convincing, positive evidence that a vasodepressive toxin derived from dying tissues induces shock or, on the other hand, conclusive proof that such toxic material could not exist.

Efforts to obtain results of the latter type have recently been reported by Roome and Wilson.⁵ A careful study was made of the effects on the blood pressure of extracts from traumatized limbs. As previous experiments of this type frequently have employed tissue extracts obtained by chemical and nonphysiologic methods which might alter materials present in an extract, the University of Chicago investigators have used a rapid and entirely mechanical method for extraction of traumatized muscle. The latter tissue was used, since the cases of large injuries to muscles are those in which shock most commonly occurs. Precautions were taken to purify the extracts by centrifugation, thus removing particles of fat and tissue which might cause sudden death by pulmonary embolism. Furthermore, the animals used for the injections were heparinized to vitiate possible blood-coagulating properties of the extracts. The latter were administered by a viviperfusion method which prevented alterations in the volume of circulating blood. With this experimental technic it was observed that intravenous injection of the extracts caused no sustained depression in blood pressure. In fact, in some instances rises in blood pressure occurred. These results are good evidence for the nonexistence of a toxic material in traumatized tissue. Further controlled investigations of this type will place the burden of proof on the school of thought that supports the toxemia theory of trauma-

matic shock. In addition, they should do much to clarify other experiments that have been conducted to determine the possible functional role of a toxic factor in certain traumatic conditions.

VITAMIN D IN COMMON FOODS

The sources of vitamin D or vitamin D effects are now so easily available and so widely distributed that the question of an adequate supply would hardly seem to concern greatly any average American. Nevertheless, pediatricians who see constantly the effects of an inadequate supply of vitamin D are inclined to deprecate the manner in which vitamin D is made available and in which it is used by the vast majority of people.

The child is taught in school that the most potent food sources of vitamin D are egg yolk and butter, yet actually there is little vitamin D in these common foods. The amounts present in egg yolk and butter vary as much as 500 per cent during the year. A recent survey of the topic by Coffin¹ points out the erroneous conceptions that prevail in the minds of many parents. There is some belief that the fresh vegetables provide adequate vitamin D, yet the vegetables contain but little vitamin D at the time of picking and Bills has shown that even a slight amount of artificial overirradiation of ergosterol will destroy acquired potency after a maximum vitamin D potency is reached. One difficulty lies in our methods of testing for the presence of vitamin D. Biologic methods in the past have not been as accurate as they are today. No doubt many a record appeared in the periodical literature that is not sustained by reinvestigation with more modern methods. Mr. Coffin has duplicated some of the earlier work with the various vegetables and other foods. His results indicate that, with the exception of egg yolk and butter, none of the ordinary foods contain any substantial amount of vitamin D. By the use of eggs and butter alone, any attempt to obtain a daily protective amount of this vitamin would probably lead to digestive disturbances if not to an unbalanced diet.

Modern man has greatly changed the conditions of his environment. Few human beings in large Northern cities obtain any substantial amount of sunshine except possibly in summer. The main source of vitamin D must therefore come to the human being from exposure to ultraviolet rays, from natural sources of this vitamin or from extra vitamin D obtained through materials that have been enhanced in their vitamin D potency. Nutritional authorities believe that man has been deprived of the vitamin D that he used to get by natural methods and that insistence on an additional source of this vitamin will be for the benefit of mankind. Certainly, so far as the growing child is concerned, some additional vitamin D is necessary everywhere.

Quite recently the thought that an oversupply of vitamin D would be developed in this manner and that

the eventual effects of this oversupply would be toxic has been reemphasized in various places. Experiments along these lines thus far reported do not warrant this belief. Clouse reported as long ago as 1932 that disastrous results from an oversupply of vitamin D did not occur in animals until the oversupply had reached at least 25,000 to 50,000 times the minimum antirachitic dose. Of course, figures are not yet available on the effects of long continued large doses for human beings. Presumably the human body possesses wide factors of safety in relationship to the assimilation of these essential substances. Thus far the evidence seems to indicate not only for vitamin D but for all the vitamins more harm in the direction of an insufficiency than in relationship to an oversupply.

Current Comment

ADDICTION TO ENDOCRINE GLAND PRODUCTS

After careful consideration of the available terms Patterson¹ feels that, with the possible exception of the French word "manie," addiction most nearly expresses some unusual manifestations that may result from the continued use of certain endocrine gland extracts. Though most of the cases of the misuse of endocrine gland extracts quoted by him are properly an "abuse," some are comparable in their psychologic content with instances of overmastery by morphine, diacetylmorphine and alcohol, for which the term "addiction" is used. In the use of thyroid gland products, which he considers first, instances of ill effects from prolonged or poorly supervised administration are numerous. The development of symptoms of hyperthyroidism is the most common of these complications. The especial danger of this is in prolonged self administration, usually aimed at the treatment of obesity. There are, however, cases in which the psychologic factor is the predominant influence. The effect of thyroid extract is to speed up metabolism and rate of energy transformation in the body, and it is easily understandable that there should be a certain tonic effect or increased feeling of well being. This appeared to be the factor influencing three of the author's patients in whom toxic symptoms of overdosage were produced. The frequency of misuse of adrenal extracts is in some ways more important because of the injection route of administration of the latter. Thus a person having asthma may develop the habit of taking large amounts of epinephrine at frequent intervals, even though he experiences little relief from the drug. The periodicity of the injections, moreover, is often striking. Also relatively small doses may be effective if given by the physician, but larger ones administered by the patient or his family may fail to give relief. A number of cases are cited to support the hypothesis that psychic factors may be largely responsible for the habitual use of epinephrine. Among them is that of

1 Coffin, Joseph. The Lack of Vitamin D in Common Foods. *J. Am. Dietet. A.* 11: 119 (July) 1935.

1 Patterson, S. W. Addiction to Endocrine Gland Extracts. *Brit. M. J.* 2: 442 (Sept. 7) 1935.

an asthmatic patient who, when deprived of his injection, committed suicide. Another case is cited in which the patient had become accustomed to giving himself from 200 to 240 injections in the twenty-four hours of the serum of Heckel, which contains epinephrine. The fear of an attack was enough to call for the injection, and the need for injection survived the cure of the asthma.² Patterson believes that physicians should be fully aware of the psychologic state and often neurotic condition of their asthmatic patients and should supervise and keep control of the treatment and instruct their patients in cleanliness and technic of injection. In the case of the gonads, the psychologic repercussions have been noted in the literature of the world from the earliest times. The attempt to regain youth has always been a favorite wish of mankind. But the knowledge of failure or lack of manly or womanly potentiality may have far-reaching psychologic effects. Such was apparently the situation in a case cited, that of a woman who for years had weekly injections of an ovarian extract. This she was accustomed to give herself, she was miserable without it, and substitution by other newer and presumably more potent extracts was stated by the patient to have no useful effect. Over the observation period of eight years she continued weekly injections but did not increase the dose or show any tendency to use other drugs. In other respects she seemed normal. The tendency to habit formation is on the whole a relatively rare complication of glandular therapy and may at times involve more the effect of the needle puncture than that of the drug. It is, however, the duty of medical men prescribing glandular extracts to exercise proper supervision and control of their use by patients. Physicians should be aware of the possible dangers so that the drug may be stopped at once if ill effects arise.

Association News

RADIO BROADCASTS

The American Medical Association broadcasts over the Blue network and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers a toast "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The next three programs are as follows:

| | | | |
|-------------|------------------------------|-----------------|------|
| October 29 | Poisonous Plants and Animals | W. W. Bauer | M.D. |
| November 5 | Hemorrhage | Morris Fishbein | M.D. |
| November 12 | Infection | Morris Fishbein | M.D. |

This program is broadcast also on the short waves through KDKA, Pittsburgh, over station W8XK, 11870 and 12,210 kilocycles.

² Flandin M. Bull. et mém. Soc. méd. d. hop. de Paris 46:116 (Feb. 3) 1930. (This case seems almost unbelievable but is correctly quoted.)

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Society News—Dr. H. Earle Conwell, Fairfield, presented a paper recently on the treatment of fractures before the Franklin County Medical Society in Russellville. Dr. Conwell addressed a joint meeting of the Elmore and Tallapoosa county medical societies at Camp Dixie on Lake Martin, recently, on "Fractures About the Elbow, Especially in Children."

Personal—Dr. Edwin P. Moon has recently been appointed state physician for prison number 1 and the tuberculosis hospital in Wetumpka.—Dr. Hampton E. Barker, Haleyville, has been named health officer of Bullock County, succeeding Dr. Leslie G. Cole, who has resigned to accept a similar position in Wetumpka.—Dr. Julius E. Dunn, Covington, Ky., has been appointed health officer of DeKalb County.

CONNECTICUT

Changes in Health Officers—Dr. Samuel Green has been appointed health officer of Southbury and Dr. Julian G. Ely, health officer of Lyme, succeeding Dr. Matthew Griswold. Dr. Jacob Edward Waldman, Middletown, has been named town health officer of Haddam.

Society News—A special dinner meeting of the radiologic section of the Connecticut State Medical Society was held September 18 during the eleventh clinical congress of the society. By-laws were discussed for adoption and other matters pertaining to the cooperation of the radiologists in the state were presented. Dr. Charles W. Perkins, Norwalk, is chairman of the section, and Dr. Max Cluman, Hartford, secretary.

ILLINOIS

Personal—Dr. Francis N. Orr has resigned from the staff of the Lincoln State School and Colony, Lincoln, after four years' service, to engage in private practice.

Society News—Dr. Edward Lee Dorsett, St. Louis, addressed the Madison County Medical Society at Madison, October 4, on "Conservative Treatment of Eclampsia."—At a meeting of the La Salle County Medical Society at Ottawa, September 26, speakers were Drs. Edward L. Cornell, Chicago, on "Fundamentals of Obstetrics", Charles E. Galloway, Evanston, "Timely Pointers on Obstetrical Delivery", and Irving F. Stein, Chicago, "Lipiodol as an Aid in Gynecologic Diagnosis."

Chicago

Personal—Dr. Jacob P. Greenhill has been elected head of the department of obstetrics at the American Hospital.—Dr. Leo M. Czaja has been appointed general superintendent of the Municipal Tuberculosis Sanitarium.

Lead Poisoning from Burning Storage Batteries—Lead fumes from a kitchen stove where storage battery casings were being burned as fuel caused the death of two children and the serious illness of five others in a family of eleven persons, the Chicago Tribune reported October 20.

Pathologic Conferences—Dr. Richard Jaffe opened a series of pathologic conferences at the Cook County morgue, October 18, on current material from the children's department of Cook County Hospital. Conferences are scheduled for November 15, December 13, January 10, February 7, March 6, April 3, May 1 and May 29.

Hospital News—The Iroquois Memorial Hospital was opened, October 17, as a branch of the Municipal Tuberculosis Sanitarium; it will be devoted exclusively to collapse therapy of tuberculosis. The hospital, which has been closed since January 1 for lack of funds, was built in 1910 as a memorial to those persons who died in the Iroquois Theater fire in December 1903.

Society News—Speakers before the Chicago Neurological Society, October 17, included Drs. Isidore Finkelman and William Mary Stephens, Elgin, Ill., on "Heat Regulation in Chronic Encephalitis."—The staff of the Sarah Morris Hospital for Children of the Michael Reese Hospital presented the program of a clinical meeting before the Chicago Pediatric Society, October 15.—At a meeting of the Chicago Society of Allergy,

October 21, Dr Samuel M Feinberg discussed "A Study of Molds and Their Relation to Allergic Diseases," and Dr Francis L Foran opened a discussion on the 1935 hay fever season

Fund for Dental Research—An anonymous contribution has made possible the establishment of a foundation for dental research in the Chicago College of Dental Surgery, the dental division of Loyola University, which will have available annually \$25,000 as a minimum. The major part of the work will be carried on in the laboratories of the dental school, while another part will be undertaken at the John McCormick Institute for Infectious Diseases. Some of the problems to be investigated will be a study of the bacteriology and histopathology of dental caries and the diseases that involve the supporting structures of the teeth as well as their effects on general health

INDIANA

Personal—Dr Joseph W Strayer, for several years resident physician at the Boehne Tuberculosis Hospital, Evansville, has been appointed superintendent of the Smith-Esteb Memorial Tuberculosis Hospital, Richmond.—Dr Werner W Duemling, Fort Wayne, has been made chief physician of the city's public schools, succeeding Dr Charles R Dancer, who held the position twenty-six years

Society News—Dr John MacMillan Townsend, Louisville, Ky, addressed the Wayne-Union Counties Medical Society in Richmond, September 19, on recent advances in urology.—At a meeting of the Floyd County Medical Society in New Albany, September 26, Dr Charles P Emerson, Indianapolis, presented a paper entitled "Why So Much Surgery in America?"—Dr Frazier N Cloyd, Danville, Ill, spoke on "Care of Common Fractures of the Arm and Leg" before the Fountain-Warren Counties Medical Society in Covington, October 3.—Dr Burrill B Crohn, New York, conducted a gastroenterologic clinic before the Indianapolis Medical Society, October 15, in the auditorium of the University of Indiana School of Medicine, in the evening he spoke at the Athenaeum on "Differential Diagnosis of Diarrheas"—Dr Edward A Oliver, Chicago, discussed treatment of cancerous lesions of the skin before the Elkhart County Medical Society, Elkhart, October 3

IOWA

Rocky Mountain Spotted Fever—Six cases of Rocky Mountain spotted fever have been reported in Iowa thus far in 1935, all in the southern part of the state. The two cases reported in September were from Lee and Linn counties, other counties involved are Poweshiek and Union. No cases were reported during August

Society News—Speakers before the Boone-Story County medical societies in Ames, September 18, included Drs Philip H Kreuscher, Chicago, on "Treatment of Fracture of the Larger Joints," and Newton D Smith, Rochester, Minn, "Fistulae and Hemorrhoids"—The Calhoun County Medical Society was addressed in Rockwell City, September 26, by Dr Johann Erwin von Graff, Des Moines, on "Miscarriages, Diagnosis, Complications and Treatment"—The Cerro Gordo County Medical Society approved the establishment of a county tuberculosis society at its meeting in Mason City, September 10. Dr Elexious T Bell, Minneapolis, spoke on "Clinical Diagnosis of Tumors of the Breast"—Dr William Wayne Babcock, Philadelphia, addressed the Johnson County Medical Society in Iowa City, October 5, on "Common Errors in Surgical Practice"—At a meeting of the Wapello County Medical Society in Ottumwa, September 17, Dr William C Newell, Ottumwa, discussed "Diseases of the Liver and Biliary Tract."—Dr Edward Jackson, Denver, will discuss "Practical Ophthalmology for Physicians and Surgeons" before the Linn County Medical Society, November 14, in Cedar Rapids

KANSAS

Physicians Needed in Civilian Conservation Corps—There are a few vacancies on the medical staff of the Kansas District, Civilian Conservation Corps. All physicians who are interested are requested to write the surgeon of the district, Fort Riley, for details

Society News—Dr Howard L Alt, Chicago, addressed the Shawnee County Medical Society in Topeka, October 6, on "Origin and Morphology of Blood Cells with Application to Disease."—The Sedgwick County Medical Society was addressed, October 1, among others, by Drs Wilbur G Gillett, Wichita, on "Foreign Protein in the Treatment of the Eye" and Willard J Kiser, Wichita, on "Pulmonary Embolism."—At a meeting of the Golden Belt Medical Society in McPherson October 3, speakers included Dr Noble E Melen-

camp, Dodge City, on "Changing Concepts Regarding the Endometrium and Their Significance"—The Tri County Medical Society, composed of Sumner and Cowley counties, Kan, and Kay County, Okla, was addressed in Winfield, September 19, by Dr Howard H Bradshaw, Boston, among others, on "Anesthesia and Surgery as Applied to Collapse Therapy in Tuberculosis"

KENTUCKY

Changes in Health Departments—Dr Fred W Caudill, Georgetown, has resigned as health officer of Scott County to become epidemiologist of the state health department. Dr Robert J Griffin Louisville, succeeds Dr Caudill in Scott County. A new health unit has been established in Lyon County with Dr Neale M Atkins, Eddyville, in charge. Dr Charles M Moore, Glasgow, who has been health officer of Barren County, has been appointed city health officer of Lexington.

MARYLAND

Personal—Dr Hosea W McAdoo, superintendent of the Springfield State Hospital, Sykesville, has resigned to accept a position at Cambridge, Mass

Dr Gunn to Give Dohme Lectures—Dr James A Gunn, professor of pharmacology and director of the Nuffield Institute of Medical Research, University of Oxford, will deliver the Dohme Lectures at Johns Hopkins School of Medicine, Baltimore, November 6-8. The titles of the lectures are "Pharmacologic and Therapeutic Properties of the Harmala Alkaloids and Their Derivatives," "Reactions of Uterine Muscle" and "Pharmacologic Syndromes"

Society News—The first fall meeting of the Baltimore City Medical Society, October 4, was designated "house officers' night," with the following speakers: Drs Thomas M Brown, Johns Hopkins Hospital, "Epidemic Meningococcus Meningitis", Harry C Hull, University Hospital, "Primary Carcinoma of the Small Intestine", Philip D Flynn, Mercy Hospital, "A Case Report of Rocky Mountain Spotted Fever", Joseph I Ostergren, Kernan's Hospital, "Xanthomatosis, Schüller-Christian Type," and Harold C Dix, Maryland General Hospital, "End Results of Complete Hysterectomy"

Visit to Home of First Medical Graduate—The memory of John Archer, M.B., who had the distinction of being the first graduate of an American medical school, was honored during the semiannual meeting of the Medical and Chirurgical Faculty of Maryland in Bel Air, Harford County, October 10. About 200 members of the faculty visited Medical Hall, seven miles from Bel Air, the birthplace and home of Dr Archer, and Churchville Cemetery, where Dr Armfield F Van Bibber, a descendant of the physician, placed a wreath on his grave. Dr Archer was born May 5, 1741, near the present village of Churchville. He received the degree of bachelor of medicine in 1768 from the University of Pennsylvania Medical Department, returning to Harford County in July 1769, where he practiced forty years. During the Revolution he was a member of the local committee from November 1774 and in December of the same year was captain of a militia company, becoming major in January 1776. In August of the same year he was a member of the convention that framed the Maryland constitution and bill of rights. He was one of the founders of the Medical and Chirurgical Faculty of Maryland in 1799 and served as a member of Congress from 1801 to 1807. He died in 1810.

MASSACHUSETTS

Personal—Dr Henry M Pollock, superintendent, Massachusetts Memorial Hospitals, has been reappointed associate commissioner of the state department of mental diseases.—Dr James G Bruce has been appointed surgeon for the police and fire departments of Springfield.

Changes in Medical Examiners—Dr John A Huffmire, Huntington, has been appointed associate medical examiner of the second Hampshire District. Dr John V Gallagher, Milford, has been named medical examiner of the sixth Worcester District, to succeed the late Dr George F Curley.

Dinner in Honor of Dr Edsall—The Harvard Medical School Alumni Association held a dinner in honor of Dr David L Edsall at the Harvard Club of Boston, October 23. Dr Edsall recently retired as dean of Harvard Medical School. James B Conant LL.D., president of Harvard University, presided at the dinner, and speakers included A Lawrence Lowell, LL.D., president emeritus of Harvard, and Dr Charles S Burwell, dean of the medical school. At a meeting preceding the dinner, addresses on "The Development of Medical

Education in the United States Since the World War" were made by Walter A. Jessup, LL.D., New York, president, Carnegie Foundation for the Advancement of Teaching, Dr. Eugene F. Du Bois, professor of medicine, Cornell University Medical School, New York, and Dr. Lawrence J. Henderson, professor of biological chemistry at Harvard. Dr. Walter B. Cannon, George Higginson professor of physiology at Harvard, presided at this meeting.

Medical School Lectures—Dr. Walter C. Alvarez, Rochester, Minn., addressed the William Harvey Society of Tufts College Medical School, October 25, on "Functional Digestive Disorders." Other meetings of the society will be addressed by the following:

- Dr. Harold E. B. Pardee, assistant professor of clinical medicine, Cornell University Medical School, New York, Arteriosclerotic Heart Disease, November 8.
- Dr. Martin H. Dawson, assistant professor of medicine, Columbia University College of Physicians and Surgeons, New York, Rheumatoid Arthritis and Osteoarthritis, December 13.
- Dr. Hiram Houston Merritt, instructor in neurology, Harvard Medical School, Boston, Syphilis of the Nervous System, January 10.
- Dr. Luther Emmett Holt Jr., associate professor of pediatrics, Johns Hopkins University School of Medicine, Baltimore, Significance of Fats in Nutrition, February 14.
- Dr. Alexander Lambert, formerly professor of clinical medicine, Cornell University Medical School, New York, Therapeutics of Drug Habits, March 13.
- Dr. Elliott C. Cutler Moseley, professor of surgery, Harvard Medical School, Boston, War Surgery, April 10.

MICHIGAN

Antimeningococcus Serum Available—The Michigan Department of Health announces that therapeutic doses of antimeningococcus serum are available to any physician on request. The new product will be handled by the regular distributors of biologic products manufactured by the department. The serum is put up in vials of 20 cc. each.

Dr. Stapleton Named Acting Dean—At the regular meeting of the Detroit Board of Education, August 27, it was decided not to appoint a dean of Wayne University College of Medicine at present. Dr. William J. Stapleton, who was appointed assistant dean at the June meeting of the board, was named acting dean until the end of the year.

Memorial to Dr. Harison—A tablet is to be mounted in a public park in Sault Ste. Marie in honor of the late Dr. Beverly Drake Harison, with the following inscription:

BEVERLY DRAKE HARISON
1855-1924

Prominent Sault Ste. Marie physician. Foremost in Michigan medical registration. One of the founders of the Upper Peninsula Medical Society—President of the Michigan Medical Society 1904.

Personal—Dr. Clarence H. Westgate, Morenci, has been appointed medical director of the Lenawee County Tuberculosis Sanatorium, Adrian, succeeding Dr. Wellington B. Huntley, now chief of the medical staff at the Southern Michigan Prison at Jackson.—Dr. Louis A. Schwartz, Detroit, has been appointed consulting psychiatrist for the Social Service Federation of Toledo, Ohio.—Dr. George W. Robinson, Detroit, has been appointed chief of the obstetrical department of St. Mary's Hospital, succeeding the late Dr. James W. Cunningham.—At the opening exercises of the University of Michigan Medical School, Ann Arbor, the honorary degree of master of arts was conferred on Dr. Andrew P. Biddle, Detroit, in recognition of a life devoted to the advancement of education and ethics in the medical profession.—Dr. Lowell S. Selling, Detroit, has been named psychiatrist in the recorder's court, succeeding the late Dr. Isaac L. Polozker.

MINNESOTA

Personal—Honorary membership in the Minneapolis Clinical Club was conferred on Dr. Adolph M. Hanson, Faribault, at a meeting, October 10. Dr. Hanson gave an address entitled "Some Aspects of the Thymus and Pineal Problems."—Dr. Clifford T. McEnaney, Owatonna, has been named physician and surgeon for the Minnesota State Public School, succeeding Dr. Allan B. Stewart, who resigned after many years' service.

Violation of Basic Science Law—Arthur N. Alexander, St. Paul, a licensed chiropractor, pleaded guilty, September 19, to a charge of practicing healing without a basic science certificate. Evidence was produced to show that Alexander had performed an abortion. Because he was unable to raise \$5,000 bail, he was confined in the Ramsey County jail. Following his plea of guilty he surrendered his chiropractic license. In view of this and of the fact that he had been in jail since his arrest, Judge Boerner imposed a suspended sentence of one year.

Society News—Dr. Melvin S. Henderson, Rochester, presented a case of atrophy of both bones of the forearm before the Minnesota Academy of Medicine, October 9, in Minneapolis. Dr. Ernest M. Hammes, St. Paul, spoke on "Spinal Cord Injuries," and Dr. Franklin R. Wright, Minneapolis, reported a case of Reflex Urinal Frequency.—Dr. Hobart A. Reimann discussed "Progress in Infectious Diseases" before the Hennepin County Medical Society, Minneapolis, October 16, and Dr. Frank H. Krusen, Rochester, spoke, October 23, on "Present Trends in Physical Therapy." The society will be addressed, October 30, by Drs. Nathaniel H. Lufkin and Henry W. Quist on "Island Tumors of the Pancreas" and "Acute Intestinal Obstruction," respectively. Dr. William Boyd, Winnipeg, will speak, November 7, on "The Decalcifying Diseases of Bone."—At a meeting of the Scott-Carver County Medical Society, September 10, at Mudbadon, speakers were Drs. Owen H. Wangenstein, Minneapolis, on acute conditions of the abdomen, Frederic E. B. Foley, St. Paul, improved operation for ureteral stone, and John F. Briggs, St. Paul, achlorhydric anemia.

MISSISSIPPI

Society News—The Adams County Medical Society was addressed recently by Dr. Jacob S. Ullman, Natchez, on "Menstruation and the Hormones."—The Jones County Medical Society was organized at the South Mississippi Charity Hospital in Laurel, recently, with Dr. Alcius J. Carter, Ellisville, president, Dr. James B. Jarvis, Laurel, vice president, and Dr. Eugene A. Bush, Laurel, secretary.

MISSOURI

University News—Dr. Theodore L. Waddle, associate director of the St. Landry Parish Health Unit, Louisiana, has been appointed assistant professor of physiology at the University of Missouri School of Medicine, Columbia, to succeed Dr. Robert W. Siddle. Dr. Robert M. Moore, instructor in bacteriology and pathology, University of Tennessee School of Medicine, has been named assistant professor of pathology to succeed Dr. Clarence C. Pfaff.

New Home for County Society—New headquarters for the Jackson County Medical Society will be included in a building to be erected soon on "hospital hill" in connection with the Kansas City General Hospital, between the present main structure and the isolation hospital. An auditorium and adjoining small rooms for committee meetings will be at the disposal of the society. The new quarters will be maintained by the city in recognition of the services of the profession to the community.

Society News—At a meeting of the St. Louis Medical Society, October 1, Dr. Sigismund S. Goldwater, New York, discussed "Handicapped Hospitals—Public and Private" and Dr. Nathaniel W. Faxon, Boston, "Voluntary Hospital Insurance." The society devoted its meeting, September 17, to a consideration of anterior poliomyelitis. Drs. Emanuel Sigoloff discussed epidemiology, Jean V. Cooke, diagnosis and treatment of the acute stage, and Clarence H. Crego Jr., the orthopedic treatment. At this meeting the name of the code and contract board was changed to the medical economics board by unanimous vote.—Dr. Louis L. Tureen, St. Louis, discussed "Pathology of Air Embolism," among other speakers before the Trudeau Club of St. Louis, October 3.—Dr. Lynn M. Garner, Tusculumbia, was chosen president-elect of the Missouri Public Health Association at its joint session with the Missouri Tuberculosis Association in Kansas City, September 5-7. Dr. Joseph F. Bredeck, St. Louis, is president. Dr. Irl B. Krause, Jefferson City, was reelected president of the Missouri Tuberculosis Association.

NEW JERSEY

Society News—The program of the Bergen County Medical Society, October 8, in Hackensack, was devoted to ophthalmologic subjects of interest to the general practitioner, speakers were Drs. Charles Littwin, Englewood, Samuel T. Hubbard, Raynold N. Berke and Arcangelo Liva.—Dr. Cornelius P. Rhoads, New York, addressed the Hudson County Medical Society, Jersey City, October 1, on "Treatment of Anemias."—Dr. Bernard I. Comroe, Philadelphia, addressed the Gloucester County Medical Society, Woodbury, September 19, on abdominal pain.—Dr. Chevalier Jackson, Philadelphia, addressed the Burlington County Medical Society, September 12, on "Bronchoscopy as an Aid to the General Practitioner."

State Board Activities—Within the past few months the State Board of Medical Examiners of New Jersey has reported the following activities, among others, in enforcing the medical practice act

Michael Jaroslaski was found guilty of practicing medicine without a license

Charles W. Remboy, an herb doctor of Butler, was found guilty of practicing medicine without a license and sent to jail for thirty days

Cleon E. Shields, Newark, pleaded guilty to practicing without a license and paid the penalty. Shields claimed to improve impaired hearing by the use of a machine called 'Auratone' which he said measures the capacity to hear and furnishes in correct volume the tones that are 'blocked out' by the impairment

Julian Cyzykowski, Englishtown, was found guilty of practicing with out a license

Among other offenders prosecuted were five druggists, one osteopath, two chiropractors, two naturopaths and two masseurs

NEW YORK

Milk-Borne Bacillary Dysentery—One hundred and thirty-one persons in a village of 500 were attacked by bacillary dysentery between August 25 and September 15 in an outbreak that was traced to the use of raw milk. The suspected dairy supplied about three fourths of the raw milk used in the village. Among 339 users of both the milk and the village water supply, ninety-three became ill, and the other cases were among those using the milk but not the water and those which could be considered contact cases. The original source of the infection is not known, according to *Health News*. Among twelve persons on the dairy farm, four were ill, but their illness occurred during the outbreak and not before it. In addition, dysentery bacilli were isolated from two other members of the household, one of whom was found to be a healthy carrier

New York City

Personal—Dr. John C. Gordon, formerly epidemiologist of the Detroit Department of Health who joined the staff of the Rockefeller Foundation in 1934, has gone to Rumania, where with a staff of laboratory and field workers he will make a study of scarlet fever

Society News—Dr. William Goldring gave a Friday afternoon lecture before the Medical Society of the County of Queens, Forest Hills, October 4, on 'Clinical Aspects of Nephritis and Hypertension'. Dr. Benjamin M. Bernstein spoke, October 18, on 'Ulcerative Colitis'.—Dr. Henri Coutard, chief of the department of roentgen therapy for cancer, Curie Institute of the University of Paris, addressed the New York Roentgen Society and the section of otolaryngology of the New York Academy of Medicine, October 16, on 'Roentgen Therapy of Epitheliomas of the Tonsillar Region, Hypopharynx and Larynx'.—Drs. Edward W. Peterson and Louise H. Meeker addressed the New York Surgical Society, October 9, on 'Tumors of the Carotid Body'.—Dr. Reuben Ottenberg addressed the Bronx Pathological Society, October 15 on 'Sepsis Arising from Trauma'.—Drs. Meyer Rosensohn and Samuel H. Geist will address the Bronx Gynecological and Obstetrical Society, October 28, on 'Toxemias of Pregnancy' and 'Gynecological Surgery,' respectively.—Drs. Edward J. O'Brien, Detroit, and Foster Murray, Brooklyn, addressed the Medical Society of the County of Kings, October 15, on 'Design for Management of Pulmonary Tuberculosis'.

Dr. Sabin to Receive Bryn Mawr Award—Dr. Florence R. Sabin, member of the Rockefeller Institute for Medical Research, has been announced as the third recipient of the M. Carey Thomas Prize of \$5,000, which is given at intervals by Bryn Mawr College, Bryn Mawr, Pa., to an American woman in recognition of eminent achievement. The presentation will be made November 2 at the college as the climax of a two day program celebrating the fiftieth anniversary of its founding. The award was founded by the alumnae association in honor of Miss Thomas and presented to her in 1922, when she retired as president of Bryn Mawr. The second presentation was to the late Jane Addams of Hull House, Chicago, in 1931. Dr. Sabin, a native of Colorado, took her medical degree at Johns Hopkins University School of Medicine, Baltimore, in 1900, and was a member of the faculty from 1902 to 1925 when she went to the Rockefeller Institute. She was professor of anatomy for twelve years and professor of histology for the next eight years. She was the first woman to be admitted to and to graduate from Johns Hopkins, the first woman intern at Johns Hopkins Hospital, the first woman member of the National Academy of Sciences and the first woman member of the Rockefeller Institute. She has received various honorary degrees and in 1929 was awarded the *Pictorial Review* Prize of \$5,000 for distinguished achievement.

NORTH CAROLINA

Personal—Dr. James Allen Whitaker, Mount Airy, has resigned as health officer of Surry County to take charge of the health department of Rocky Mount.—Dr. Clarence H. White, Kenansville, has been appointed district health officer in charge of Avery, Yancey and Watauga counties

Campaign Against Hookworm—The International Health Division of the Rockefeller Foundation, New York, has made available \$12,000 to the state board of health to finance a campaign against hookworm. Dr. Alvin E. Keller, Nashville, Tenn., will direct the work, which will include a survey and campaign of prevention and prophylaxis.

OHIO

Changes at University of Cincinnati—Dr. John H. Foulger, associate professor of pharmacology at the University of Cincinnati College of Medicine, has resigned to join the staff of the Haskell Laboratory for Toxicological Research, Wilmington, Del. Dr. Norman A. David, assistant professor of pharmacology, University of West Virginia School of Medicine for the past three years, has been appointed assistant professor in the department at Cincinnati.

Personal—Dr. Carl Watson, Findlay, has been appointed works progress administrator for Ohio.—Dr. James F. Busby, Northville, Mich., has been appointed superintendent of the Licking County Tuberculosis Sanatorium, Newark, succeeding Dr. Donald E. Yochem, who resigned to enter private practice.—Dr. Harry W. Wertz, Montpelier, was appointed health officer of Williams County to succeed the late Dr. William A. Held, West Unity.—Dr. Will M. Hoyt, Hillboro, has been appointed health officer of Highland County to succeed Dr. John L. Walker.

Henry Hoffman Arrested—Dayton, Ohio, newspapers of October 9 report that Henry Hoffman of Rosewood, Ohio, was arrested at Tippecanoe City, October 9, on an indictment charging him with practicing medicine illegally. A bond of \$100 with one Christopher Metzgar as surety, was furnished by Hoffman and he was released. It is reported that Hoffman accepted a fee for medical service and also prescribed certain medicines, although the man is not a physician. The paper states, also, that Hoffman was convicted on the same charge at Laton a year ago and fined \$50. It is claimed that in writing prescriptions for medicines, Hoffman makes a prescription in such a form that it cannot be filled at a drug store, but the patient—or victim—must go to an alleged agent of Hoffman. According to the report, the agent selling Hoffman's nostrums in Tippecanoe City is Metzgar, the man who put up the \$100 bond. The files of the Bureau of Investigation of the American Medical Association contain a clipping from a Greenville, Ohio, newspaper of June 1934, reporting plans for a retrial in the state's case against one Henry Hoffman of Verona, an alleged faith healer.

OKLAHOMA

Personal—Dr. John T. Looney, Tishomingo, has been appointed health officer of Johnston County.—Dr. Max H. Grow has been appointed physician to the Oklahoma Agricultural and Mechanical College at Stillwater.

Society News—At a meeting of the Southern Oklahoma Medical Association at the Central State Hospital, Norman, September 3, speakers included Drs. Carl T. Steen of the hospital staff, on 'Sterilization as Applied to the Insane', Wann Langston and Bert E. Mulvey, Oklahoma City, 'Symposium on the Heart and Interpretation of the Electrocardiogram', and Ray M. Balyeat, Oklahoma City, 'Use of Iodized Oil in Treatment of Asthma'.—Dr. Samuel R. Cunningham, Oklahoma City, addressed the Cleveland County Medical Society, Norman, October 1, on 'Fractures of the Knee and Elbow: Their Diagnosis and Treatment'.—Dr. E. Rankin Denny, Tulsa, addressed the Tulsa County Medical Society, October 14, on 'Significance of Blood Cholesterol Determinations in Hypometabolism'.

PENNSYLVANIA

Society News—A graduate conference was held at Wilkes-Barre General Hospital recently with clinics in the morning and lectures in the afternoon. Guest speakers were Drs. George W. Crile, Cleveland, Emanuel Libman, New York, and Emil Novak, Baltimore.—Dr. Francis C. Grant, Philadelphia, addressed the Cambria County Medical Society, Johnstown, October 10, on 'Diagnosis and Surgical Treatment of Brain Tumors'.—Dr. Milton H. Cohen, Lewistown, addressed the Mifflin County Medical Society, Lewistown, September 5,

on Female Sex Hormones and Their Clinical Application"—Drs Arthur M Shipley and Maurice C Pincoffs, Baltimore, conducted the annual fall clinic of the Fayette County Medical Society, Uniontown, October 21

Philadelphia

Faculty Changes at the University—Dr Carl Edwin Bachman, Montreal, Canada, has been appointed assistant professor of obstetrics and gynecology at the University of Pennsylvania School of Medicine. Dr Bachman is a native of Pennsylvania and a graduate of the university. Drs Edward H Campbell and Harry P Schenck have been promoted to be assistant professors of otolaryngology.

Society News—Among speakers at a meeting of the Philadelphia Academy of Surgery, October 7, were Drs John O Bower, Newlin F Paxson and Harold A K Mengle, who presented "A Preliminary Report of the Presence of Clostridium Welchii Antitoxin in the Blood of Patients Who Have Recovered from Peritonitis, the Result of a Perforated Appendix."

Opening of Woman's College—Dr Chevalier Jackson, recently elected president of the Woman's Medical College of Pennsylvania, and Dr Louise Pearce, New York, made addresses at the opening of the new session, September 26. The following appointments were announced:

Dr Esther M Greisheimer formerly associate professor of physiology, University of Minnesota professor of physiology

Dr Hartwig Kuhlbeck formerly professor of anatomy at the University of Breslau Germany acting professor of anatomy

Ben King Harned Ph.D. formerly chief of the division of pharmacology University of Tennessee College of Medicine Memphis professor of pharmacology

Versa Viola Cole Ph.D. formerly research assistant Ohio State University College of Medicine Columbus assistant professor of pharmacology

Marion Fay Ph.D. formerly lecturer of chemistry University of Texas School of Medicine professor of physiological chemistry

Marie Anderach Ph.D. formerly of the pathological chemistry laboratory University Hospitals State University of Iowa assistant professor of physiological chemistry

Dr Mary Bickings Thornton, formerly part time professor of anatomy at the college was made professor emeritus. To improve the facilities of the library a full time librarian has been appointed. Dr Jackson succeeds Mrs James Starr who resigned as president to devote more time to the financial problems of the institution as chairman of the executive committee.

SOUTH CAROLINA

Society News—At the annual meeting of the Seventh District Medical Association in Manning, September 19 speakers included Drs Verling K. Hart and George Aubrey Hawes, Charlotte N.C. on 'Bronchoscopic and Clinical Observations in Bronchial Obstruction and Bronchiectasis' and 'Urologic Symptoms Resulting from Pathologic Conditions of the Female Urethra,' respectively, and Edgar F Fincher Atlanta "Tumors of the Brain"—Drs George T McCutchen and Lucius E Madden addressed the Columbia Medical Society September 9, on "Hyperinsulinism" and "Pulmonary Aneurysm" respectively

TENNESSEE

Infant Mortality—In an effort to reduce the high infant mortality rate in Memphis, the city health department has increased the number of its clinics for well infants under the direction of a full time pediatrician, Dr Beulah M Kittrell, formerly of Knoxville. The rate of 112 per thousand live births in 1934 was the highest in the United States for cities of 30,000 population and over, it was said. For the first five months of 1934 the rate was 121.6 and for the same period of 1935 it was 94.7

Health at Nashville—Telegraphic reports to the U.S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended October 12 indicate that the highest mortality rate (19.4) appears for Nashville and that the rate for the group of cities as a whole was 10.5. The mortality rate for Nashville for the corresponding week of last year was 16.5 and for the group of cities was 10.2. The annual rate for the eighty-six cities for the forty-one weeks of 1935 was 11.4 and the same rate appears for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Society News—Dr Louis Levy addressed the Memphis and Shelby County Medical Society recently on 'Vincent's Angina.'—Drs Jesse B Swafford and Edward E Reisman addressed the Hamilton County Medical Society Chattanooga,

October 3, on "Dementia Praecox" and "Diagnostic Observations on Ectopic Pregnancy," respectively.—At a meeting of the Hardin, Lawrence, Lewis, Perry and Wayne county medical societies in Hohenwald recently, speakers were Drs William C Boyce, Flat Woods, on "Mechanism and Management of Normal Labor", William R. Cate, Nashville, "Clinical Diagnosis and Significance of Irregularities of the Heart" and Ernest W Goodpasture, Nashville, "Value of Vaccine in Poliomyelitis"—Dr Richard A Barr, Nashville, addressed the Gibson County Medical Society recently on "Abdominal Operations on Children."—Drs Roy H Ruble, Limestone, and Edward T West, Johnson City, addressed the Washington County Medical Society, Johnson City, September 5, on "Diabetes Mellitus" and "Carcinoma of the Cervix," respectively

VIRGINIA

New Building for Medical College—Through an anonymous gift of \$300,000 and a federal grant of \$239,850, the Medical College of Virginia, Richmond, will shortly begin construction of a new outpatient clinic and laboratory building seven stories high. The first four floors will be for clinics and the upper floors for laboratories in pathology, bacteriology, biochemistry, public health and preventive medicine. It is expected that a hospital will be built later adjoining the clinics.

Society News—At the quarterly meeting of the Augusta County Medical Association in Staunton, recently, speakers were Drs Lemuel Nelson K. Bell, Waynesboro on 'Medical and Surgical Problems in China', Clarence P Obenchain, Staunton 'Relief of Suffering During Confinement,' and Kenneth Maxcy, University, 'Infantile Paralysis'—Drs Otis T Amory and Edward L Alexander, Newport News, addressed the Mid-Tidewater Medical Society, Gloucester Courthouse, recently, on 'Indigestion' and 'Antigens and Vaccines and Their Uses,' respectively—Dr Collins D Nofsinger, Roanoke, addressed the Montgomery, Floyd and Giles county medical societies at a joint meeting in Saint Albans, recently, on 'Diagnosis and Treatment of Myocarditis'—At the quarterly meeting of the Southside Virginia Medical Association in Burkeville, September 10, speakers included Drs Thomas F Wheeldon, Richmond, on "Value of the Cystine Content Determination in the Treatment of Arthritis", Wilkins J Ozlin, South Hill, 'Diagnosis in Diseases of the Chest', and Roy K. Flannagan, Richmond, "Medical Economics"

WASHINGTON

Society News—Dr Henry Schmitz, Chicago addressed the King County Medical Society, October 21, on 'Early Diagnosis and Indications for Treatment of Carcinoma'—Dr Alfred A Strauss, Chicago, addressed a special meeting October 25, on 'Surgical Diathermy for Treatment of Carcinoma of the Rectum and Stomach'—At a meeting of the Klickitat County Medical Society, September 27, Dr Dmitry V Ogievsky, Klickitat was elected president and Dr Frank G LeFor, Goldendale, secretary. A woman's auxiliary was organized with Mrs Allen Bonebrake, Goldendale, as president. Plans were made for an active campaign for control of diphtheria and smallpox—Dr John C Lyman, Walla Walla, was elected president of the Walla Walla Valley Medical Society at a meeting in Walla Walla October 10, Rudolf A Clemen, president of Whitman College, made an address

WISCONSIN

Society News—Dr Maurice Brodie, New York delivered the Lippitt Memorial Lecture of the Medical Society of Milwaukee County, October 11, on "Poliomyelitis: Its Transmission, Prevention and Treatment," and Dr Walter P Blount spoke on 'After-Care of Paralytic Poliomyelitis'—Speakers at a meeting of the Ninth Council District Medical Society at Wisconsin Rapids recently were Drs William F Wilker, Iola, on 'Complete Avulsion of the Scalp', James K Trumbo, Wausau 'The Incidence of Allergy in the Etiology of Nasal Polyps,' and Norbert Enzer, Milwaukee, "Relation of Pathology to the Practice of Medicine."

State Society Awards—The Council of the State Medical Society of Wisconsin at the annual session in Milwaukee, September 19, presented its award for distinguished service to the society, the medical profession and public health to Edward Asahel Birge, LL.D. Madison president emeritus of the University of Wisconsin, and to Dr Arthur Jackson Patek Milwaukee, founder and for several years editor of the *Wisconsin Medical Journal*. Dr Birge now 84 years old was for fifty years associated with the university as instructor in natural history, professor of zoology, dean of the college of arts and

sciences (1891 to 1918) and president (1918 to 1925). Dr Patek is a former president of the Medical Society of Milwaukee County and the State Medical Society of Wisconsin and was originator and for twenty-six years secretary of the medical defense fund of the state society.

GENERAL

Examinations in Dermatology—The American Board of Dermatology and Syphilology will hold oral examinations, May 11-12, 1936, in Kansas City, Mo., during the annual session of the American Medical Association. The written examination for Group B will be held on Saturday, March 14, in various cities throughout the country, applications for this examination should be filed before Jan. 15, 1936 with the secretary, Dr. Clarence Guy Lane, 416 Marlborough Street, Boston.

Report of National Research Council—During the past year the National Research Council has made 116 grants totaling \$50,359.50. The largest single amount, \$12,600, was expended for medical sciences. Ninety-six postdoctorate fellowships have been supported at a total expenditure of \$221,927.73. Among these, ten were in the medical sciences. The principal enterprises aided in the medical field were research on problems of sex, in which emphasis will now be laid on synthetic production of hormones, investigations on narcotic drugs at the universities of Michigan and Virginia, a survey of research in the United States on the gonococcus and gonococcal infections, now nearing completion, and a world survey of tropical diseases and facilities for studying them, now in process of publication.

Annual Meeting of Dietitians—At the eighteenth annual meeting of the American Dietetic Association in Cleveland, October 27-31, the program will include addresses by the following physicians:

Dr. William P. Murphy, Boston, Deficiency States—Anemia
Dr. Wingate Todd, Cleveland, Food for Fitness
Dr. Henry J. John, Cleveland, Treatment of Diabetic Children
Dr. Charles H. Eyermann, St. Louis, Allergy and Its Relation to the Dietitian
Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, Food Fads and Fallacies
Dr. Charles C. Higgins, Cleveland, Dietary Management of Urinary Lithiasis
Dr. Donald J. Barnes, Detroit, Newer Developments in the Treatment of Rickets
Dr. Victor G. Heiser, New York, World Wide Adventures in Nutrition

Society News—Dr. Daniel C. Patterson, Bridgeport, Conn., was elected president of the New England Surgical Society at its annual meeting in Manchester, N. H., September 27-28. Dr. David W. Parker, Manchester, vice president, Dr. John M. Birnie, Springfield, secretary, and Dr. James R. Miller, Hartford, Conn., treasurer. The next meeting will be held in Bridgeport.—Dr. Charles M. Griffith, Washington, D. C., was elected president of the Association of Military Surgeons of the United States at its annual meeting in New York, October 5. Dr. Harold D. Corbuser, Plainfield, N. J., was elected one of the five vice presidents to fill the vacancy left by Dr. Griffith's advancement to the presidency. Among other speakers at the meeting, Dr. Dean Lewis, Baltimore, read a paper on the history of military surgery.

Western States Have Highest Automobile Fatality Rates—With a 15 per cent increase over 1933, automobile fatalities reached a new high point in 1934, when 33,980 persons were killed in or by motor cars, causing a death rate of 26.9 per hundred thousand of population. In addition, 1,789 persons were killed in collisions between automobiles, railroad trains and street cars. These figures compare with 29,323 deaths in 1933 and a rate of 23.3 per hundred thousand of population. Nevada's automobile death rate of 73.4 was the highest in the nation. Wyoming was second, 45.25, Arizona third, 44.85, and California fourth, 42.62. The bureau of the census directs attention to the fact that the states with the highest rates are in the West rather than the thickly populated Eastern states. While this situation may be brought about by the deaths of transients, there are no statistics at present to prove this point. The lowest rate in the United States (14.6) was for Rhode Island. Only three states, Kansas, Delaware and New Hampshire, showed a decrease in the death rate last year compared with 1933. Gains over 1933 in the remaining states ranged from Connecticut's 2.07 per cent to Montana's 72.13 per cent. With the exception of Vermont the percentage of gain was greatest in the Middle West, Far West and South. New Mexico's gain of 42.12 per cent was the second largest in the nation. Mississippi was third, with an increase of 41.02 per cent. Vermont had a gain of 38.52 per cent, in contrast to New Hampshire's decrease of 23.14 per cent. In Illinois fatalities increased 17.04 per cent last year compared with 1933. The gain in New York was only 3.49 per cent.

Sept 28, 1935

A Survey of Health Services During the King's Reign

The report of the ministry of health for 1935 contains a review of the health services during the twenty five years of the king's reign. The ministry was established in 1919 to take over the functions of national health insurance and the local government board. National health and pensions insurance is pronounced one of the most memorable developments of public health. In England and Wales 16,450,000 persons are insured, and in the last ten years more than \$750,000,000 has been distributed in sickness and maternity benefits and more than \$450,000,000 in medical benefits. The provision of pension benefits has steadily expanded and now includes 664,000 old age pensions to persons between the ages 65-70, 657,000 widows' pensions (supplemented by 271,000 additional allowances with respect to children) and 15,000 orphans' pensions.

The expansion of local government services is shown by the fact that the total expenditure has risen from \$735,000,000 in 1911 to \$2,535,000,000 in the last completed year of the account. The London County Council alone expended \$190,000,000, a sum comparable to the budget of some nations. Thus expenditure on health is defended as a long term investment. The standardized death rate from all causes has fallen from 13.2 per thousand in 1910 to 9.3 in 1934. Some changes in mortality, which may be attributed in part to the operation of public preventive and clinical services, are shown in the accompanying table.

Changes in Mortality

| | 1910 | 1933 |
|---|-------|-------|
| Infant mortality per 1000 live births at ages 0-1 years | 10.5 | 6.4 |
| Death rates per million children living at ages 5-15 | 2,491 | 1,882 |
| Standardized death rates per million from tuberculosis | | 9 |
| Respiratory | 888 | 63 |
| Nonrespiratory | 434 | 160 |
| Standardized death rates per million from typhoid | 53 | 5 |

Systematic services for the prevention and treatment of tuberculosis and for maternity and child welfare have come into being, and schemes to aid the blind are now operating all over the country. In 1910 there was no mental deficiency service. In 1913 accommodation was provided for severe cases, the training and employment of defectives, and the treatment of early mental illness. Other advances noted are the provision of postgraduate medical training facilities and the promotion of medical research. Nineteen thirty-four was a record year in two respects: the death rate from all forms of tuberculosis and the infant mortality were the lowest on record. But there was no decline in the maternal mortality rate, and measures are now being taken by the ministry to grapple with this problem. The continued decline in the incidence of smallpox (variola minor) became still more marked in 1934, when the number of cases was fewer than in any year since 1918. For the first time in six years London was free from smallpox on July 12, 1934, so that the smallpox hospital could be closed.

Postgraduate Medical Study in London

The facilities for postgraduate study in London, whether by physicians in general practice or by those who want to cultivate some special branch, are considerable. The twelve undergraduate medical schools are almost entirely devoted to the teaching of students but at times provide a postgraduate course, in some cases confined to their old students and in others open to the profession. At five of the medical schools an intensive

week-end course of lectures for graduates is now in progress and takes place every year at the opening of the medical session in October. In the main, graduate teaching is done at the general hospitals that are not undergraduate medical schools, and at the special hospitals. Most important is the recently established British Postgraduate Medical School which was opened in May by the king. It contains 388 beds, which are being rapidly increased to 534 by the erection of a new block. The school has no special departments, since it was thought best that graduates who require instruction in the specialties should obtain it at the numerous special hospitals of London. There are four departments—medicine, surgery, obstetrics and gynecology—each under the control of a professor appointed by the University of London, assisted by readers, also appointed by the university, and assistants appointed by the school. It is hoped to include on the staff the leading teachers and authorities available in London and the provinces and also some from other parts of the world. Refresher courses of an intensive character are provided for physicians in general practice. They last a fortnight and are generally held in the summer months. But the most important part of the teaching is that provided for graduates from all parts of the world. In this a departure has been made. Graduate instruction has usually consisted almost entirely of courses and lectures covering a set syllabus. This will form part of the instruction, but more importance is attached to providing the students with a large amount of clinical material at which they can work under instructors, all of whom have special experience. Carefully prepared clinical lectures are given from time to time. The students also attend regular pathologic and radiologic conferences and discussions between the different departments. The department of pathology not only takes part in the clinical work but provides demonstrations on laboratory procedures. The fees for the ordinary hospital practice, including tuition, are \$26 for one month, \$52 for three months and \$78 for six months. For the fortnight refresher courses the fee is \$26.

Unlike the British Postgraduate Medical School, in which almost all the teaching is done in one hospital the Fellowship of Medicine and Postgraduate Medical Association arranges for teaching in some fifty general and special London hospitals. Regular courses, lasting from one to four weeks, are arranged in general medicine and surgery. Courses in pediatrics, diseases of the chest, heart or nervous system, gynecology, obstetrics, ophthalmology, dermatology, proctology, orthopedics, fractures, psychiatry, urology, physical therapy, venereal diseases, and anesthetics are given at the special hospitals devoted to these specialties. In addition, various special hospitals make arrangements for courses.

The West London Postgraduate College has been established since 1895. The work is carried on at the West London Hospital, which is entirely devoted to postgraduate teaching. Graduates are appointed clinical assistants for three or six months without extra charge. A special clinic for the treatment of venereal diseases (male and female) is held all day. Operations at which graduates are allowed to assist take place daily at 2 p. m. The fees for hospital practice, including all ordinary demonstrations and lectures are \$10 for one week, \$30 for one month, \$45 for two months and \$60 for three months. Instruction in the administration of anesthetics is given at the rate of \$15 a month.

The North-East London Postgraduate College is attached to the Prince of Wales's General Hospital, which contains 228 beds and is entirely devoted to graduate teaching. Facilities are afforded to graduates for general hospital work or for work in special branches. The fee for general hospital practice is \$10 for one month, and \$25 for three months. For the special departments the fee is \$15 for one month and \$30 for three months.

A postgraduate school of radiotherapy was established in 1930. It is held at the Radium Institute and at the Mount Vernon Hospital. The Institute of Medical Psychology holds courses in psychotherapeutic theory and method. A five-week introductory course of twenty lectures, for which the fee is \$15, is now in progress. The London School of Hygiene and Tropical Medicine holds a six months course for the Diploma in Tropical Medicine and Hygiene, which lasts from October to June. It consists of instruction in clinical and laboratory work and in tropical hygiene. The fee is \$200.

The Treatment of Casualties of the Quetta Earthquake

The appalling disaster of the Quetta earthquake has been reported in a previous letter to *THE JOURNAL*. As the medical authorities decided that recovery of the bodies buried beneath the debris would have been dangerous, the exact number killed is not known, but it is estimated at 40,000 in the whole country-side involved, a district of 130 by 20 miles. In Quetta itself out of a population of 45,000 between 20,000 and 30,000 were killed. The government took prompt and efficient measures for succoring the survivors. Supplies were sent and refugee camps were established. The treatment of the many cases of serious fracture was excellent. At the Mayo Hospital, Lahore, the organization was of the standard of the highly specialized fracture clinics of Europe or America. All cases of fracture of the spine, pelvis or femur were treated in wards allotted to each kind of fracture. Balkan frames fitted with adjustable pulleys, weights and traction cable were available for all cases. Several dozens of fractured femurs were treated by stainless steel pins transfixing bone. Cases of fractured pelvis were treated by pin or wire traction applied to both lower limbs. The cases of fractured spine were reduced on a special table and given the best possible chance. Old-fashioned padded splints were conspicuous by their absence. This work was carried out under the directions of Lieut-Col. V. R. Mirajkar, professor of operative surgery, King Edward Medical College, and superintendent of the Mayo Hospital.

PARIS

Sept. 23, 1935

Changes in Social Insurance Law

In a recent letter attention was called to the many complaints regarding the administration and the deficits in some of the primary disbursement offices of the social insurance organization. To balance its budget, the French government has attempted to make economies in all its departments. Although only in existence since 1930, the social insurance law, which combines sickness and maternity compensation and invalidity and old age pensions, has been modified a number of times. The question of social insurance had been carefully studied for ten years before being made compulsory. The practical application of the principle has revealed many defects. One of the chief differences between the law in France and the laws of other European countries is that the insured sick individual can choose his own medical adviser, who is paid directly by the insured. The latter then presents his statement of expenditures for physicians, dentists, drugs and apparatus to the primary *caisse* or bureau to which he belongs and is reimbursed to the extent of about 85 per cent. Owing to dissatisfaction on the part of both the insured and the medical profession a complete revision of the law has been ordered by the secretary of labor, to whose department the execution of the law is assigned. To understand some of the important changes, a brief outline of the present organization will precede the list of changes proposed by M. Froissard as outlined in the September 15 issue of the *Siècle médical*.

The premiums from the insured and those from their employers are forwarded every three months by the latter to

a central office in the capital of each department, there being eighty-six departments in France. The insured and the employer each pay a sum based on the average total earnings of the insured. There are four classes of premiums, varying according to the annual wages of the insured. Every insured person who earns 15,000 francs (about \$1,000) and has no children is included in the social insurance law. If there is one dependent child, the limit is higher (20,000 francs) and this rises to 25,000 for those with three or more children. Thus about 60 per cent of all workers are subject to the law.

The departmental receiving office divides its receipts into two parts. One of these is sent to the primary caisses or disbursement centers, which pay sickness, death and maternity claims. Any money left over is sent to another bureau, which up to the present time formed a union with other similar caisses of the corresponding department, to act as a reinsurance company if there should be a deficit in one of its constituent primary caisses. It was the original intention of the law's sponsors that any excess of receipts over expenditures of the primary caisses should be expended for public hygiene purposes, but this has never been done.

The second half of all receipts by the central departmental bureau is sent to primary saving centers, to be paid out for invalidity and old age benefits. Since a large percentage of the insured will not reach the old age limit (60 years) for many years to come, the excess of receipts over expenditures has been placed in a government guaranty fund, to which the state itself has also added 540 million francs (about 36 million dollars), so that as old age pensions become due in future years there may be ample funds to meet the demand. One of the cuts in force since August is to diminish this sum contributed to the guaranty fund (for invalidity and old age pensions) from 540 to 140 million francs. There has been considerable criticism about the manner in which the rapidly accumulating guaranty funds have been invested in unprofitable enterprises. The fact that it will be many years before the majority of those now insured will reach the age of retirement has been one of the defects of the present law.

One of the first reforms proposed by the committee of experts chosen to suggest changes in the law was to cut down the government's contribution to the guaranty fund from 540 to 140 million francs. A reduction in the amount of the annual premiums paid by the insured and the employers was found to be impossible because the diminished receipts would not suffice to pay the various kinds of benefits.

Instead of having so many central receiving offices for each department with a corresponding large number of officials, there will be only one office of this kind for each postal region. This will be a vast saving in administrative costs. An effort to limit the number of primary distributing centers or caisses was unfortunately abandoned, so that many remain each with only a few hundred insured. The unions for reinsurance of the primary caisses or disbursement centers have been discontinued and the money formerly sequestered for these organizations will be devoted to public hygiene work. The reinsurance will in the future be the duty of the central guaranty fund. Thus about 30 per cent of the receipts for sickness, death and maternity benefits can now be utilized in preventive work. This figure (30 per cent) is somewhat chimerical, because many of the primary caisses or disbursement bureaus for sickness, death and maternity will probably have a deficit during the present year and surely will next year.

The discontinued reinsurance bureaus exercised an important control over the expenditures of these primary disbursement offices, because the reinsurance bureau guaranteed the lower bureaus' finances. A control will now be lost, hence this modification of the law has been vigorously criticized. Allowance for pharmaceutical specialties, of which there are

thousands in France, have been reduced from 85 per cent to 50 per cent. This will be a great saving for the disbursement offices.

Many simplifications of the now cumbersome paper work have been ordered.

Death benefits, instead of being paid by the same office which reimburses sickness and maternity claims, will now be paid by the savings fund.

The unemployed will be considered as regularly insured provided they have registered for work as soon as the latter can be obtained.

The method of remittances of premiums has consisted in purchasing special social insurance stamps at a postoffice. This will be dispensed with. One needs only to read the list of changes in the present social insurance law to realize that although it may be of benefit to those whose earnings do not provide for sickness, maternity, death, invalidity and old age, the execution of such a law demands an incalculable amount of paper work ("paperasserie" in French) and a very large staff of officials.

Energetic Antinoise Campaign in Paris

Continuing his energetic efforts to suppress unnecessary noise, the prefect of police has just issued instructions regarding the treatment of the city's inveterate radio sinners. If one's neighbor's radio shrieks at an hour when sleep is, or should be, the chief task of quiet-loving citizens, the police can be informed by telephone and an officer will be sent at once. After investigation, a report will be made and legal proceedings commenced to suppress further radio sinning. Much has already been accomplished here, by restricting the hours during which automobile horns can be used. The chief offender is still the motorcycle, but this question is being studied and soon Paris will seem like a village at night.

First Brucellosis Congress Held in France

The growing importance of *Brucella* infections has led to the formation here of a society, composed of clinicians, bacteriologists, hygienists and veterinary surgeons. The first meeting of this society was held at Avignon, in the south of France, in June. It is well known now that Malta fever, now commonly called undulant fever or brucellosis, and contagious abortion in cattle are caused by the same etiologic agent, *Brucella*. In human beings, brucellosis is commonly transmitted through raw cow's milk or unpasteurized dairy products. Among the latter are to be especially mentioned, in France, cheese made from the milk of goats.

In addition to members of the French medical and veterinary professions, there was a relatively large number of Italian and English visitors.

The first day was devoted to the clinical aspects of undulant fever. Cannavo of Libya reported his own case of this form of infection, characterized by the appearance on the fiftieth day, of a choroiditis. Chantegreil added three cases all verified by a positive seroreaction, complicated by a phlebitis in one case. Meerseman observed an acute encephalitis confirmed at necropsy, the inflammatory lesions being chiefly situated in the subcortical tissues.

Bruschettini of Genoa, Italy, has found that an egg medium is the simplest to employ in the bacteriologic diagnosis. He had been able to confirm the existence of two types of *Brucella* infection. Barbary and Faure-Brac of Nice strongly advocated the more widespread use of the intradermal reaction. Undulant fever is the most serious disease that threatens the raising of cattle, sheep and hogs. Every prophylactic measure must be employed, in the form of the intradermal reaction, to prevent spread of the infection to human beings and among animals.

Guign of Bologna, Italy, was enthusiastic about the use of a specific vaccine containing from 5 to 10 million bacteria per injection, which is followed in the majority of cases by a rapid regression and cure of human brucellosis. Picard of Arles (France) was not so enthusiastic, as he had had only a large number of failures.

Cambessedes of Paris believed that anaphylactic shock reaction in the form of vaccination therapy and chemotherapy were strongly indicated in the treatment of human brucellosis. A number of other speakers were of the opinion that such a form of treatment is not to be recommended, because it is apt to cause exacerbations of a most serious character.

Dubois and Sellier of France have used as a prophylactic measure a polyvalent antibrucellosis vaccine during the past five years in 5,000 people exposed to animal infection. This form of prophylaxis ought to be used by every butcher, veterinarian and cattle raiser.

Julien of France warmly advocated centers like the one at Joyeuse, in which those suffering from undulant fever can be isolated. Many of these patients live in mountainous regions, are difficult to get to and thus cannot be given the daily observation, which is needed.

Every small community should be provided with a diagnostic and prophylactic center. These stations would have an important educational effect on the rural population in showing how the disease is recognized and treated. The economic loss in regions where undulant fever exists is enormous. If the infected individuals can be returned to work in twenty-five days, as is now possible at the Joyeuse center, the money spent in such a direction will be amply repaid.

Louis Roux, a bacteriologist of Lausanne, called attention to the association of brucellosis and tuberculosis. In seven mammary cases this combination was present. The Bang bacillus seems to be the primary invader.

Finzi of Italy does not believe that dead vaccines are of any value and uses only living ones. Preventive vaccination of cattle is the only way of checking the spread of brucellosis.

Hayat of Tunis found that in laboratory animals infected with brucellosis a superadded tularemia might occur. He had observed agglutination reactions toward both infections in the blood of such animals.

Julien of Paris stated that in cases of prolonged fever one ought always to take into account the possible presence of kala-azar, which is far more widespread in southeastern France and Mediterranean countries than is brucellosis.

In resolutions passed at the close of the congress, the establishment of an international bureau for the study of human and animal brucellosis was decided on.

The Birth Rate and Mortality in Some European Countries

According to Moine's statistics reported at the July 23 meeting of the Academy of Medicine, the decreased ratio of births to deaths dates back as far as to the decade 1811-1820, when there were only 318 births to 10,000 inhabitants. This figure gradually decreased to 281 from 1851 to 1870, during which most other European countries registered an increase in their natality, which continued to the end of the nineteenth century. From 1871 to 1880 there were only 254 births to 10,000 inhabitants, as compared to 308 in Switzerland, 323 in Belgium, 354 in England, 362 in Spain, 369 in Italy and 391 in Germany. Since 1880 there has been a decrease in the number of births in all these countries, so that in 1933 the last places in the list were occupied by England (144) and Germany (147). Only Spain and Italy showed a relative increase to 262 and 232 respectively. The number of births since 1880 has decreased by 23.5 per cent in Spain, 35.8 per cent in France and Italy, 46.8 per cent in Switzerland, 48.9 per cent in Belgium, 59.3 per cent in England and 62.5 per

cent in Germany. The coefficients of fecundity for each 10,000 women between the ages of 15 and 49 years was 868 in 1901 for France, 1,040 for England and 1,440 for Germany. These figures show a marked decline in 1933. The coefficients of fecundity in 1933 as compared to those of 1901 show a decrease of 64.6 per cent for Germany, 50.2 per cent for England, 44.2 per cent for Switzerland, 35.5 per cent for Italy and only 29.1 per cent for France. This improvement in France is the result of the work of various organizations that have encouraged the raising of larger families. As to the number of deaths for each 10,000 inhabitants in 1933, the percentage for France was 158, Germany 112, Italy 137, England 123, Spain 164, Belgium 134 and Switzerland 114. If one considers the mortality of each country according to the population distributed according to the type (city and country), France between 1920 and 1922 had only 149 deaths, against 165 in Germany, 226 in Spain and 156 in Italy.

If the age of those who have died is taken into consideration, one finds a marked decrease in the mortality at certain ages since 1900 in France. This diminution of mortality has been in part due to a smaller number of deaths from tuberculosis. In 1880 there were 500 deaths from this disease per hundred thousand inhabitants in Paris. At the present time there are only 176, a decrease of 66 per cent as compared to that of the general mortality of 48 per cent. As a result of the fight against venereal diseases in France, more than 20,000 new-born infants are saved annually.

Two problems the solution of which will be aimed at in the future are first, to increase the natality by decreasing the mortality, and, secondly, to struggle against infant mortality.

BERLIN

(From Our Regular Correspondent)

Sept 2, 1935

Treatment and Prognosis of Severe Gastric Hemorrhages

The "Treatment and Prognosis of Severe Gastric Hemorrhages" was discussed at a recent session of the Berlin Medical Society. Professor Umber emphasized that few clinical reports with detailed statistics have been published. This accounts for the discrepancy between the German opinion, supported by Morawitz, Bergmann and others, to the effect that death from a severe bleeding induced by an ulcer is rare, and the English statistics that give a mortality of from 18 to 23 per cent. Umber therefore had statistics prepared on the cases occurring in his clinic during the past fifteen years, which disclose that, in 1,852 gastric and duodenal ulcers, 433 severe manifest hemorrhages occurred, associated with vomiting of blood and tarry stools. In forty-one cases death occurred as a result of excessive hemorrhages. Thus it appears that the mortality from hemorrhages was 9.5 per cent and the mortality from hemorrhages associated with ulcers was 2.2 per cent. Hence Umber considers the mortality from severe hemorrhages due to ulcer as much higher than is commonly supposed. A large percentage of the fatal cases occurring in his clinic presented severe hemorrhages due to erosion of the walls of the gastroduodenal artery, the gastrica sinistra or the gastrica dextra. If the hemoglobin drops to from 20 to 30 per cent serious danger for the patient arises. From the standpoint of treatment, rest and narcotics are indicated, also hemostatic, hypertonic solutions of sodium or calcium salts. If the stomach is full of blood, and a tendency to vomit arises, gastric lavages with ice-water are advisable, since they not only give the patient subjective relief but have also a hemostatic effect. Nutrition should be ample, for long continued undernutrition furthers the hemorrhagic tendency. For this purpose iced butter pellets are recommended, in addition, doses of vitamin C twice daily. Rectal clysmas of high caloric content are however, rejected as they increase the secretion of

gastric juice In pronounced anemia, blood transfusions are advisable, sometimes repeated on several successive days No more than 500 cc should be injected, since, as a result of an increase in pressure, thrombi may easily develop A blood transfusion should be compulsory before every operation When the hemorrhage has been checked, iron preparations should be given to combat the anemia Of 433 cases of gastric hemorrhage, an operation was performed in thirty-nine, resulting in seven fatalities, in three of these patients it was found later that a carcinoma had been present As the source of hemorrhage, Umber found much more frequently a gastric ulcer than a duodenal ulcer, which agrees with the statements of others Severe hemorrhages due to ulcer should be treated first internally, in recurrences and in ulcer hemorrhages that show no tendency to thrombose (suspicion of arterial hemorrhage) an operation is indicated.

From the surgical point of view, Professor Reschke likewise found hemorrhages due to ulcer more frequent than is generally supposed A hemorrhage may be regarded as grave when it is doubtful whether a patient can be saved by internal treatment. Reschke had good success with surgery and only a slight mortality from pneumonia and peritonitis The mortality from hemorrhage due to ulcer is higher in men than in women The normal method of operation is resection If a blood transfusion is allowed to precede an operation, the intervention is not dangerous It is his observation, however, that blood transfusion often does not check the hemorrhage but, on the contrary, makes the next hemorrhage worse Danger of a recurrence of a hemorrhage is especially great two days after the transfusion The operation should not be undertaken until the patient has recovered his strength as the result of a large transfusion of from 1,000 to 1,500 cc., together with a like amount of solution of dextrose If the patient does not recover his strength, the transfusion should be allowed to suffice. Early operation during the first twenty-four to forty-eight hours, as proposed by Finsterer, does not appear necessary

In the discussion, Professor von Bergmann emphasized the difficulty of distinguishing between mild and severe hemorrhage He is opposed to morphine because it retards the gastric motility and through collection of blood in the stomach leads to vomiting, it also increases nausea He has not observed that the tendency to hemorrhage is accentuated by hunger The fewer remedies that are given to promote circulation in connection with hemorrhage, the easier it is to check the flow of blood Since the introduction of the preoperative blood transfusion, von Bergmann is no longer inclined to oppose an operation. Professor Kalk presented statistics of his hospital department in Berlin It appears that, in ten years, of 157 severe hemorrhages, thirteen, or 8.3 per cent, ended fatally, but only in six of the thirteen fatal cases was hemorrhage the sole cause

The Physiology of Work

Professor Basler, an authority on the physiology of work, who has been appointed to a chair at the University of Breslau, spoke recently on the "Tasks of the Physiology of Work" As the two chief tasks of the physiology of work he designated (1) the determination of the most favorable, least fatiguing work method, and (2) the discovery of the persons who are best adapted for a certain form of activity To perform these tasks adequately, and particularly to measure the amount of effort necessary to do a certain piece of work, requires more than ordinary care in research The most universal type of work is walking The principal movements are those of the sole of the foot and of the hip The movements in the intermediate joints needed to round out the principal movements are of secondary importance. In walking, the lifting of the body about 4 cm. brings about a frictional resistance

of the joints The energy consumption, measured by respiratory metabolism, varies with the number and length of the steps The optimum is 35 calories (body weight 80 Kg) with the number of steps at 87.5 and the length of step 58.7 cm. The most practical load under the most favorable conditions is 43 per cent of the body weight The most favorable load is that of the back, whereas the exertion, without corresponding increase of the energy consumption, is greater, the greater, in any activity, the static component becomes (for example, carrying a weight in the hand) The work to be performed may become thereby absolutely impossible. There is as yet no perfectly reliable method for the objective measurement of fatigue The unconscious shortening of the length of step after a long march is of considerable value as a criterion of fatigue. This is determined by counting the number of steps taken in a specified stretch The second method is based on the "decrease in the physiologic height" of a person The examinee is allowed to walk past a board on which are pasted a number of horizontal strips 1 cm. wide The examiner with a field-glass notes the strip that is in line with the crown of the head of the examinee at the highest point while the examinee is walking

With regard to utensils, for example, the wheelbarrow commonly used in Europe is much less practicable than the Chinese wheelbarrow, in which the center of gravity of the load lies directly over the axis of the wheel

Basler called attention to a certain test of fitness for a given type of labor which he considered important, namely, a test of the ability to stand on one's feet for long periods of time. To determine quickly the resistance of the vascular apparatus of the legs of an examinee, the examiner measures, instead of the increase in volume, the increase in the girth of the lower leg using for the purpose a flexible tape, which is fastened about the leg and which a special device keeps at a uniform tautness The girth of the leg can be read from a scale. If the leg of an examinee increases unduly in size after he stands for one hour, he is advised to avoid those occupations which require a workman to stand for long periods

AUSTRALIA

(From Our Regular Correspondent)

Sept. 3, 1935

Sixth Australian Cancer Conference

The influence of the fourth International Congress of Radiology held at Zurich in July 1934 was felt at the sixth Australian Cancer Conference at Canberra, May 14-17 Another feature of the conference was the more active part played by the Royal Australasian College of Surgeons This is a significant development, as there was a danger that the element of bureaucracy was playing too large a part in the proceedings Cancer of the breast was discussed from the surgical and radiotherapeutic aspects but no finality was achieved owing to difficulties of comparing the statistics

RECOMMENDATIONS REGARDING STANDARDIZATION

1 It is desirable to introduce in Australia, wherever it is not already in use, the international method of measuring x-rays in terms of the roentgen unit, as prescribed by the International Congress of 1934

2 There should be provision for the testing of x-ray equipment in all the characteristics essential for its effective operation

3 There should be in Australia a single primary standard for the measurement of the international roentgen unit.

4 There is urgent need in Australia for facilities for the testing, examination and calibration of scientific apparatus and instruments used in radiotherapy, and for the carrying out of scientific investigations connected with (a) the purely physi-

cal aspects of radiotherapy, (b) the biophysical aspects of radiotherapy, and (c) the performance of x-ray equipment

5 Such facilities should exist in several centers and in particular in the two largest cities—Sydney and Melbourne—where provision should be made for the continuance and extension of existing physical services

6 In order to secure the best results, provision should be made for close coordination and for the dissemination of relevant information

7 The federal government should subsidize these activities financially

8 The work should be coordinated and controlled by a special board, the constitution of which should be arranged by the Commonwealth Department of Public Health and the Council of Scientific and Industrial Research in consultation

Professor Laby of Melbourne in support of the recommendations drew attention to the remarkable developments in the physics of cancer treatment that had taken place abroad. In England, France, America, Germany, Sweden and other countries a number of physical research laboratories to serve cancer clinics have been set up. These laboratories carry out roentgen and radium measurements and investigate the use of x-rays of higher voltage than those hitherto used and the possibilities of artificially produced radioactivity

He stressed the necessity of obtaining some degree of accuracy in the measurement of x-rays and gamma rays from radium used therapeutically and to introduce into Australia the international method of measuring x-rays in the terms of the roentgen unit. This involves (a) the measurement of the quantity (dosage) of x-rays by air ionization methods, (b) the determination of their quality according to rule 5 of the International Recommendations, and (c) measurement of radium, radon and gamma rays

He drew attention to the fact that precision of physical measurements cannot be made by methods that can be specified for all time, and they must be in the control of those who are engaged in original research in the branch of physics to which the standards relate, and who are leaders in that branch of physical research. This principle is fully accepted in the national physical laboratories referred to. If Australia is not to be behind these countries, it will need to do the same.

Rule 5 of the international recommendations states "The specification of dosage shall include a statement of the quality of the radiation. For exact physical measurements the quality of the radiation may be specified in terms of the complete absorption curves in copper or aluminum. For most practical purposes the quality may be expressed by the first and second half value layers of the same materials

Activities of Commonwealth Radium Laboratory

The increase in the use of radon can be gaged by the quantities issued by the laboratory at Melbourne (table 1)

Ninety two per cent of the radon issued during 1934 was mounted in the form of needles. Of the remainder, 7 per cent was issued in tubes for gynecologic use and 1 per cent in small gold implants. Of the radon issued in needles 66 per cent was issued in needles of 0.8 mm platinum filter, 25 per cent in needles of 0.5 mm platinum filter and 1 per cent in needles of 0.4 mm platinum filter. The tendency toward the use of the more heavily filtered needles is evident from these figures. At the Melbourne Hospital and St Vincent's Hospital radon needles of 0.8 mm platinum filter are used exclusively

Protection arrangements have been intensified by the following

(a) All lead screens behind which radium or radon is handled are to be increased in thickness to 4 inches of lead

(b) Experiments are being carried out with a semiautomatic radon purification plant, which, if found satisfactory will

replace the existing plant. Such a semiautomatic plant would greatly reduce the exposure received by the operator, and if the plant can be made sufficiently compact, it could be surrounded by several inches of lead

(c) A device is being installed whereby any leakage of radon into the air of the laboratory will automatically cause the

ventilating fan to be set in operation. Such a device should assist in keeping the laboratory free from radioactive contamination

Pernicious Anemia in Australia

It is interesting to note in the Australian Year Book the death rate from pernicious anemia and the effect thereon of the introduction of liver therapy

Prior to 1928 deaths from pernicious anemia were not recorded separately in the Australian Year Book. Consequently, prior to that date the total includes other anemias as well as chlorosis

In that year Minot and Murphy announced their discovery. It is interesting also to note the dates on which the work of Minot and Murphy appeared. Preliminary observations had been published in *THE JOURNAL* (Aug 14, 1926, p 470, Sept 3, 1927 p 759) but the work on the reticulocyte response was published in 1928 in the *American Journal of the Medical Sciences* (175 581 [May] 1928). That the death rate should have been almost halved the same year is an indication of the ready acceptance of the new treatment by Australian physicians

One effect noted in Australia is the quickening of interest in the anemias generally, their more complete investigation and

TABLE 2—Yearly Deaths from Pernicious Anemia

| Year | Males | Females | Total | Other Anemias and Chlorosis |

| 1930 | 94 | 141 | 235 | 50 |
| 1931 | 121 | 169 | 290 | 52 |
| 1932 | 133 | 153 | 286 | 30 |

their more thorough classification for treatment purposes. It is possible that this has accounted for the apparent rise in the figures for the late years shown in table 2

International Union Against Cancer

Correspondence had passed between the commonwealth government and the international union in connection with the suggested adhesion of Australia to it. The commonwealth government had decided to defer any action regarding adhesion to the International Union or the nomination of official representatives on the council of direction until the matter had been discussed by the Australian Cancer Conference, and the president of the international union had been informed accordingly

The conference, after discussing the matter, expressed the opinion that the question of joining the International Union Against Cancer was a matter for the cancer organization in each state to decide on individually, and that it be left in the hands of each state organization to take such action as it considered desirable in this respect

RIO DE JANEIRO

(From Our Regular Correspondent)

Sept 15, 1935

The First Reported Case of Undulant Fever

Dr Jose Guilherme Lacorte, head of the laboratories of the Instituto Oswaldo Cruz, in a lecture before the Academia Nacional de Medicina of Rio de Janeiro reported bacteriologic and serologic studies in a case of undulant fever, the first one seen in Rio de Janeiro. The bacteria developed on a solid culture medium placed in an atmosphere overcharged with carbon dioxide. The medium was prepared according to Huddleson's technic. The bacteria were not motile in broth cultures of twenty-four or forty-eight hours examined by the hanging drop method, except for exaggerated brownian movement. They are rod shaped with round ends varying between 0.2 and 0.4 micron in width and 0.5 and 1 micron in length and are gram negative. Colonies that develop in petri dishes containing ordinary gelose after forty-eight hours resemble pin heads between 0.2 and 0.4 mm in diameter, they are convex, transparent, humid, shining and smooth, with complete and regular contours and a center darker than the rest of the colony. As they grow older they turn brown and their borders become irregular. The bacteria, when placed in simple broth, produce slight turbidity after twenty-four hours and intense turbidity and precipitation after forty-eight hours, in gelatin at 20 C they produce moderate proliferation without liquefaction, on potato medium they grow poorly and turn the medium dark, they fail to form indole and to reduce nitrates to nitrites and they do not form acid or gas. The organism proliferates well in Huddleson medium, when it contains fuchsin in the proportion of 1 to 25,000, thionine in the proportion of 1 to 30,000 or methyl violet in the proportion of 1 to 100,000. The speaker concluded that the organism was *Brucella melitensis*, however, the patient was a hog slaughterer, a fact that would make more plausible, his infection with *Brucella suis*. The fact that the bacteria grew in a medium placed in an atmosphere overcharged with carbon dioxide, which is a characteristic of *Brucella abortus*, is also surprising. However, the bacteria isolated by the speaker behave as *Brucella melitensis* with respect to the formation of hydrogen sulphide and in not taking certain stains.

Local Insulin Therapy in Pleural Thickening

Dr Santos Fortes reports satisfactory results with local insulin therapy in about 100 cases of pleural thickening. The treatment consists of subcutaneous injections of insulin in doses varying from 0.2 to 1 cc, associated with the administration of sugar, either in water or in candies. The injections are made at the level of the pleural lesions and are given every other day in a number varying from twelve to ninety. Satisfactory results were obtained in thirty of a group of thirty-four cases. The treatment was discontinued in the remaining four because of hypersensitivity to insulin. Hypoglycemia, which appeared in some cases during the course of the treatment, was controlled by the administration of sugar. The treatment gives the best results in postpneumonic pleural thickening of the type described by Morquio and also in some cases similar to those described by Bacmeister as chronic pneumonia, the prognosis of which has been considered as fatal. The speaker, with Argerich, believes that the local action of insulin therapy is probably due to a trophic action of insulin on the tissues by which glycoexis in the tissues is promoted.

JAPAN

(From Our Regular Correspondent)

Aug 29, 1935.

Vital Statistics

In its recent report, the statistical bureau of the cabinet states that according to the census of 1930 the death rate of the nation was less than 20 per thousand of population. The death rate of infants was highest, having been 140 for boys and 124 for girls per thousand babies. When boys grow to be 16 or 17 years old and girls 17 or 18 years old, only three fourths of them have survived their contemporaries. Just half the number of men of 54 or 55 and women of 55 or 56 have died, and one fourth of the men of 69 or 70 and women of 73 or 74 survive. The average span of life is roughly estimated to be 50 years, but the average span of life of babies under 1 year old was 44.82 years in boys and 46.54 years in girls. When they were 3 years old their life expectancy was the longest, that is, 52.54 years for boys and 53.59 years for girls. As the age advances the expectancy gradually grows less and at the age of 20 men had 40.18 years and women 42.12 years more to live. When men were 32 years old and women were 33 or 34 the figures showing their ages and their life expectancy was just the same. At the age of 50 men had 18.49 years more to live, and women 21.67 years.

The death rate by age groups is shown in the following table

| Ages | Male | Female |
|------|-------|--------|

Junior Nurses

The government believes that expenses incurred by patients should be lessened. Patients now generally have to pay the nurses almost as much as the hospital charges and sometimes even more. Sometimes an expert nurse is not required and a cheaper nurse will do. The home office sees much demand for a practical nurse and will train "junior nurses," who will be able to attend the sick in place of the licensed nurses for a much smaller fee. Junior nurses will be trained for three months in the government institute, while the licensed nurses will be required to take a course of training for two years.

Nearsightedness in Japanese Students

The results of the annual physical examination at the various schools for 1933 has been a matter of great surprise. In the middle grade schools, attended by boys and girls from 12 to 18 years of age, the percentage of the nearsighted has increased in the last twenty years to 36.35 from 15.97 in boys and to 34.56 from 10.40 in girls. In the vocational schools the increase shows almost the same percentage. In colleges and universities about 35,000 students are nearsighted that is, fifty students out of a hundred. The cause of this increase has been investigated by various medical and educational bodies, such as the school physicians' society, the health bureau of the educational office and the Japan Ophthalmologic Association. They say the cause is, in part the small type used in dictionaries and textbooks, which children are obliged to read to prepare for

the entrance examinations to the various schools. They are burdened daily by the keen competitive examinations after they reach the age of 10 because of the surplus population all over the country. Secondly, modern students have weaker constitutions than the previous generations. Thirdly the old fashioned buildings are poorly lighted. School buildings now have improved lighting, but the dwelling houses often are far from being well lighted. A sensation was thus created in Tokyo and the authorities have set about to prevent this condition in future generations. On the other hand, some are of the opinion that the children's eyes are weakened in infancy because most of the Japanese children are carried on the backs of maid servants, often facing the strong rays of the sun. With such a vital problem, a general movement for prevention is expected to be undertaken soon by the nation as a whole.

Medical Economics

In the prefecture of Shizouka, with a population of about 1,700,000, reports were made Oct 1 1930 by medical practitioners on various topics. According to this report about twenty nine patients visit a practitioner daily in cities and about thirty four patients in rural districts, giving an average of 30.5 patients. This includes the old and the new cases at the ratio of 69 old cases to 1 new case. Therefore, on an average, about four new patients come to a practitioner each day. The number of the practitioners in this prefecture is 1,013 in all, including 167 general practitioners, 536 physicians, ninety-eight surgeons and sixty one obstetricians. Of these patients 88 per cent could not afford to pay a fee. Out of every thousand patients there were 132 between 15 and 19 years old, and they comprised the largest number.

Marriages

WILLIAM E. DAWSON Hookerton N C, to Miss Winnie Davis Reel of Morehead City, at Kinston, August 25

WILLIAM MORGAN CHEW Waynesboro Va, to Miss Katharine L Salmon of New York, August 14

Deaths

August Caille * New York Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1877. College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1881, emeritus professor of pediatrics, New York Post-Graduate Medical School of Columbia University, fellow of the American College of Physicians, past president of the American Pediatric Society, delegate to the International Medical Congress in Berlin, aged 81, at various times on the staffs of the Convalescent Home for Babies Sea Cliff, N Y, New York Post Graduate Hospital, Isabella Home and Hospital and the Lenox Hill Hospital, where he died, October 10, of cerebral hemorrhage.

Simeon Edward Joseph * Portland, Ore, University of California Medical Department, 1877, dean emeritus, emeritus professor of nervous and mental diseases, and one of the founders of the University of Oregon Medical School, past president of the Portland Medical Society and the Portland Academy of Medicine, at one time member of the state legislature medical superintendent of the Oregon State Hospital for Insane, 1881-1883, and the Oregon State Hospital, Salem, 1886-1887, for many years on the staff of the Good Samaritan Hospital, aged 85, died, August 23.

Alvin Walter Klein * Stockbridge, Mass, Cincinnati College of Medicine and Surgery, 1889, member of the American Psychiatric Association served during the World War physician to the Austen Riggs Foundation, at one time chairman of the board of health of Greenwich, Conn, and on the staff of the Greenwich (Conn) Hospital, aged 67, died suddenly, September 27, of coronary occlusion.

Willis Newton Smith, Phoenixville, Pa., Western Pennsylvania Medical College, Pittsburgh, 1892, member of the Medical Society of the State of Pennsylvania, past president of the Chester County Medical Society, on the staff of the Phoenixville Hospital aged 77 died, September 6, in the Chester County Hospital, West Chester, of nephritis.

Peter John Zeglio * Plainfield, N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1882, fellow of the American College of Surgeons on the staffs of the Muhlenberg Hospital, Plainfield and the Somerset Hospital, Somerville, aged 75, died, August 3, of chronic myocarditis and arteriosclerosis.

Neil McLean * Devils Lake, N D, Minneapolis College of Physicians and Surgeons, medical department of Hamline University 1906, past president of the Devils Lake District Medical Society, served during the World War, aged 57 died September 3, in a hospital at Livingston, Mont, of pneumonia and cerebral hemorrhage.

Walter J. Leach * New Albany, Ind., Louisville (Ky) Medical College, 1897, president of the Indiana State Medical Association and formerly councilor of the Third District, past president and secretary of the Floyd County Medical Society, on the staff of St. Edward's Hospital aged 73, died, September 29, of heart disease.

John E. Nevill, Bonham, Texas, Memphis (Tenn) Hospital Medical College, 1900, member of the State Medical Association of Texas, past president of the North Texas District Medical Society and the Fannin County Medical Society, aged 66 died, August 31 in a sanatorium in Paris, of amyotrophic lateral sclerosis.

James Donald McKinnon, Port Chester, N Y, McGill University Faculty of Medicine, Montreal, Que., Canada, 1924 at one time instructor and professor of pathology at the University of Wisconsin Medical School, Madison, aged 36, died September 5, at the United Hospital, of an accidental overdose of paraldehyde.

Henry Herbert Healy, Grand Forks, N D, Rush Medical College Chicago 1892 member of the North Dakota State Medical Association, fellow of the American College of Surgeons surgeon to St Michael's Hospital and the Deaconess Hospital aged 65, died September 1, of carcinoma of the prostate.

Franklin Elijah Spear * Woodsville, N H, University of Vermont College of Medicine 1903, past president of the Grafton County Medical Society, served during the World War, aged 62, on the staff of the Cottage Hospital, where he died September 5, of acute hemorrhagic pancreatitis.

The conference, after discussing the matter, expressed the opinion that the question of joining the International Union Against Cancer was a matter for the cancer organization in each state to decide on individually, and that it be left in the hands of each state organization to take such action as it considered desirable in this respect.

RIO DE JANEIRO

(From Our Regular Correspondent)

Sept. 15, 1935

The First Reported Case of Undulant Fever

Dr Jose Guilherme Lacorte, head of the laboratories of the Instituto Oswaldo Cruz, in a lecture before the Academia Nacional de Medicina of Rio de Janeiro reported bacteriologic and serologic studies in a case of undulant fever, the first one seen in Rio de Janeiro. The bacteria developed on a solid culture medium placed in an atmosphere overcharged with carbon dioxide. The medium was prepared according to Huddleson's technique. The bacteria were not motile in broth cultures of three-four or forty-eight hours examined by the hanging drop method, except for exaggerated brownian movement. They are rod shaped with round ends varying between 0.2 and 0.4 micron in width and 0.5 and 1 micron in length and are gram negative. Colonies that develop in petri dishes containing ordinary gelose after forty-eight hours resemble pin heads between 0.2 and 0.4 mm in diameter; they are convex, transparent, humid, shining and smooth, with complete and regular contours and a center darker than the rest of the colony. As they grow older they turn brown and their borders become irregular. The bacteria, when placed in simple broth, produce slight turbidity after twenty-four hours and intense turbidity and precipitation after forty-eight hours in gelatin at 20 C they produce moderate proliferation without liquefaction, on potato medium they grow poorly and turn the medium dark, they fail to form indole and to reduce nitrates to nitrites and they do not form acid or gas. The organism proliferates well in Huddleson medium, when it contains fuchsin in the proportion of 1 to 25,000, thionine in the proportion of 1 to 30,000 or methyl violet in the proportion of 1 to 100,000. The speaker concluded that the organism was *Brucella melitensis*; however, the patient was a hog slaughterer—a fact that would make more plausible his infection with *Brucella suis*. The fact that the bacteria grew in a medium placed in an atmosphere overcharged with carbon dioxide which is a characteristic of *Brucella abortus*, is also surprising. However, the bacteria isolated by the speaker behave as *Brucella melitensis* with respect to the formation of hydrogen sulphide and in not taking certain stains.

Local Insulin Therapy in Pleural Thickening

Dr Santos Fortes reports satisfactory results with local insulin therapy in about 100 cases of pleural thickening. The treatment consists of subcutaneous injections of insulin in doses varying from 0.2 to 1 cc, associated with the administration of sugar, either in water or in candies. The injections are made at the level of the pleural lesions and are given every other day in a number varying from twelve to ninety. Satisfactory results were obtained in thirty of a group of thirty-four cases. The treatment was discontinued in the remaining four because of hypersensitivity to insulin. Hypoglycemia, which appeared in some cases during the course of the treatment, was controlled by the administration of sugar. The treatment gives the best results in postpneumonic pleural thickening of the type described by Morquio and also in some cases similar to those described by Bacmeister as chronic pneumonia. The prognosis of which has been considered as fatal. The speaker, with Argerich, believes that the local action of insulin therapy is probably due to a trophic action of insulin on the tissues by which glycopexis in the tissues is promoted.

Aug. 29, 1935

Vital Statistics

In its recent report, the statistical bureau of the cabinet states that according to the census of 1930 the death rate of the nation was less than 20 per thousand of population. The death rate of infants was highest, having been 140 for boys and 124 for girls per thousand babies. When boys grow to be 16 or 17 years old and girls 17 or 18 years old, only three-fourths of them have survived their contemporaries. Just half the number of men of 54 or 55 and women of 55 or 56 have died, and one-fourth of the men of 69 or 70 and women of 73 or 74 survive. The average span of life is roughly estimated to be 50 years, but the average span of life of babies under 1 year old was 44.82 years in boys and 46.54 years in girls. When they were 3 years old their life expectancy was the longest, that is, 52.54 years for boys and 53.59 years for girls. As the age advances the expectancy gradually grows less and at the age of 20 men had 40.18 years and women 42.12 years more to live. When men were 32 years old and women were 33 or 34 the figures showing their ages and their life expectancy was just the same. At the age of 50 men had 18.49 years more to live, and women 21.67 years.

The death rate by age groups is shown in the following table.

| Ages | Male | Female |
|------|-------|--------|
| 0 | 140.1 | 124.1 |
| 1 | 43.1 | 42.1 |
| 2 | 22.4 | 22.7 |
| 3 | 0.4 | 7.1 |
| 10 | 2.0 | 3.0 |
| 15 | 6.0 | 7.3 |
| 18 | 0.1 | 10.1 |
| 20 | 0.8 | 10.6 |
| 23 | 0.3 | 10.2 |
| 24 | 0.0 | 0.9 |
| 30 | 7.4 | 8.9 |
| 40 | 0.0 | 10.1 |
| 50 | 17.5 | 12.6 |
| 60 | 80.7 | 24.2 |
| 70 | 80.4 | 57.7 |
| 80 | 170.2 | 138.5 |
| 90 | 341.4 | 322.7 |
| 100 | 004.8 | 021.2 |

Junior Nurses

The government believes that expenses incurred by patients should be lessened. Patients now generally have to pay the nurses almost as much as the hospital charges and sometimes even more. Sometimes an expert nurse is not required and a cheaper nurse will do. HAINES' GOLDEN TREATMENT

A Long-Lived Medical Swindle Debarred from the Mails

A particularly heartless swindle that has been operated through the United States mails for over fifty years has finally had the mails closed to it. On August 26 1935, the Postmaster General, on evidence satisfactory to him, declared that the Dr J W Haines Company, the Golden Specific Company and their officers and agents as such of Cincinnati, Ohio, were engaged in conducting a scheme for obtaining money through the mails by means of false and fraudulent pretenses, and that in view of this, the postmaster at Cincinnati was instructed to stamp 'Fraudulent' and return to the writers all letters addressed to the concerns named and refuse to pay any postal money order drawn to the order of the concerns or parties involved.

The "Dr Haines Golden Treatment" used to be known as the "Golden Specific" before lying on or in the trade package carried with it a risk of prosecution. For over half a century mothers, wives and sisters have been led to believe that they can cure their loved ones of the drink habit by the secret administration of the Haines Golden Treatment. Never in all this period has a case of drunkenness been cured by such means. But swindlers who exploit "liquor cures" know full well that in the very nature of the case the victims who learned that they had been defrauded would never complain because of the publicity that is inseparable from such complaints. Next to the vampires who used to sell narcotic mixtures under the specious claim that they would cure the drug habit the most heartless swindlers in the "patent medicine" field are the exploiters of preparations sold under the claim that the drugs may be administered without the knowledge of the patient and yet will cure the patient of the drink habit.

Eighteen years ago—October 27, 1917—there was published in this department of THE JOURNAL an article on the Haines Golden Treatment in which it was characterized as "a cruel humbug." In the article there were given the results of an analysis made by the A M A Chemical Laboratory, showing that the alleged cure was essentially a mixture of milk sugar and starch, with a small amount of red pepper and a minute amount of ipecac.

A year previously (1916) the state chemists of North Dakota analyzed the same preparation and reported that the stuff consisted of about 75 per cent of milk sugar, 15 to 20 per cent of wheat starch, with ipecac, capsicum and cascara present. There was no cascara found by the chemists of the American Medical Association but the composition of nostrums is notoriously variable.

In November, 1929, the National Better Business Bureau issued a special bulletin to periodical publishers on the Haines Golden Treatment, pointing out the fraudulent claims made for the product and stating that the exploitation of the Golden Treatment was contrary to the public welfare. In the same year the Federal Trade Commission ordered a complaint against the Dr J W Haines Company, because the concern was advertising that its compound would cure a person of the liquor habit without the patient's knowledge. The Commission proceeded against the Haines concern, charging that the representations and claims made were false and misleading and deceived and misled the purchasing public. Two years later the Haines concern entered into a stipulation with the Federal Trade Commission to correct and revise its advertising copy, its literature and form letters so as to eliminate all the objectionable material. The Commission reported that the concern had agreed that it would not at any time in the future publish or distribute such objectionable representations or "any statement representation or implication that is equivalent or similar in form or in substance to those eliminated" from the advertising material. Of course, a quackish concern of this type could hardly be expected

to keep its word, and, in fact, it was still making the fraudulent claim that the Commission had objected to up as late as the time that the Post Office Department proceeded against them.

The Haines preparation could not be reached under our present inadequate Food and Drugs Act, because the exploiters were shrewd enough not to make false or fraudulent claims on or in their trade package. They confined their lying to the newspapers and cheap magazines that would accept their advertisements—and the Pure Food and Drugs Act does not penalize fraudulent newspaper advertising.

The Hon. Karl A Crowley, Solicitor of the Post Office Department in his memorandum to the Postmaster General recommending the issuance of a fraud order, brings out some interesting facts regarding this long-lived swindle. According to the memorandum, the sole owner of the business at the present time is one Richard J Goettle, Jr. The fraud was "first launched in 1882 at Cincinnati, Ohio, by J M Boyle and Dr Haines, who later sold out his interest to Mr Boyle." As far as we have been able to find out, there never was a Dr J W Haines in Cincinnati.

It seems that in 1913 Boyle sold the business to the father of the present owner. Richard J Goettle, Jr., has operated the fraud since his father's death in 1931.

The Solicitor's memorandum states further that, according to Goettle's own claim, the annual gross receipts have approxi-

DRUNKENNESS CURED

It is Now Within the Reach of Every Woman to Save the Drunkard

By a new discovery which can be given in tea, coffee or food. It does its work so silently and surely that while the devoted wife, sister or daughter looks on, the drunkard is reclaimed even against his will and without his knowledge or co-operation. Send your name and address to Dr J W Haines, 1012 Glenn Bldg., Cincinnati, Ohio, and he will mail enough of the remedy free to show how it is used in tea, coffee or food and that it will cure the dreaded habit quietly and permanently. Also full directions how to use it, books and testimonials from hundreds who have been cured and everything needed to aid you in saving these men and dear to you from a life of degradation and ultimate poverty and disgrace.

MISS MARY ROBERTS.
The above is a picture of Miss Mary Roberts, 1012 Golden Gate Ave., San Francisco, Cal., who successfully cured her brother after he had led a drunkard's life for years. She most heartily recommends Golden Specific to every woman and wants to do everything in her power to help others save the drunkard.

advertisements. The one on the left appeared about thirty six years ago (Cosmopolitan December 1899) the one on the right was published in 1935.

No More Whiskey Drinking

Home Treatment That Costs Nothing To Try

Odorless and Tasteless
Any Lady Can Give
It Secretly at Home in
Tea, Coffee or Food.

If you have a husband, son, brother, father or friend who is a victim of liquor it should be just the thing you want. All you have to do is to send your name and address and we will send absolutely FREE, in plain wrapper, a trial package of Golden Treatment. You will be thankful as long as you live that you did it. Address Dr J W Haines Co., 383 Glenn Building, Cincinnati, Ohio.

For fifty years this fraudulent cure has been advertised. Here is a reproduction (reduced) of two typical

dated \$78,000! Of this, 95 per cent was derived from mail-order sales and about 5 per cent from drug store sales. The mail-order sales were promoted by advertisements that were published in about a hundred daily newspapers and about fifty magazines—publications that were willing to share the profits of this fraud in order that the contact could be made between the victims and the swindler. A typical advertisement read in part as follows:

HE HATES WHISKEY NOW

AN ODORLESS AND TASTELESS TREATMENT DID IT

'Any lady can give it secretly at home in tea, coffee or food and it costs nothing to try. If you have a husband, son, brother, father or friend who is a victim of whiskey, beer or wine, send your name and address to Dr J W Haines Co., 490 Glenn Bldg., Cincinnati, Ohio, and they will send you absolutely free in plain wrapper a trial package of this wonderful treatment. What it has done for others is an example of what it should do for you when used as directed. Write today and be thankful all your life.'

Those who answered the advertisements were sent the so-called trial package and a form letter, together with a pamphlet. The form-letter stated that the powder could be given secretly, but that even if the liquor addict knew that he was getting it, the result would not be changed, because this treatment does not affect his wish, since the purpose of the

preparation is to relieve the craving for liquor " The same letter emphasized

No one in your family need know the victim is being given Golden Treatment. The victim himself should never know it but allowed to believe that he quit of his own free will Remember that the passion for drink may be handed down by heredity Aid not only the living man but those who may live after him

The pamphlet that accompanied the form-letter purported to show the injurious effects of alcohol on the brain, heart, stomach, liver, nose, eyes and kidneys. Lurid colored pictures such as used to be published in the common-school textbooks of the 90's were scattered through the pamphlet.

A question blank also accompanied the form-letter, pamphlet and trial package, which called for the answers to several questions as to age, weight, sex, occupation and habits of the addict. The blank carried a statement that the questions should be carefully answered "in order that we may fully understand condition of patient." The facts were, however, that no attention whatever was paid to the symptom blank and, in fact, there was no one connected with the Haines outfit who was qualified to express an opinion, for, as the memorandum to the Postmaster General brings out, neither Goettle nor anyone connected with the enterprise had any medical training. The memorandum states that the so-called Golden Specific or Golden Treatment contained the following ingredients in powder form:

| | |
|---------------|------------------|
| Milk sugar | Prickly ash bark |
| Pleurisy root | Angelica root |
| Bayberry | Red pepper |
| Ginger | |

The so-called treatment came in three strengths—"Mild," "Regular" and "Extra-Strong." They all contained the same ingredients, but the proportions varied. Milk sugar made up the bulk of all of them, but whereas the "Mild" treatment contained about 11.5 grams of milk sugar in the 15-grain powder, the "Extra-Strong" contained 8 grains, while the Mild contained 1 grain of ginger, the Extra-Strong contained 2 grains, and whereas the Mild contained $\frac{1}{40}$ of a grain of red pepper, the Extra-Strong contained $\frac{1}{80}$ of a grain.

Richard J. Goettle, Jr., the sole owner of this fraud, did not appear at the hearing. He was represented by an attorney and the hearing lasted two days. Goettle's attorney offered no testimony with respect to the efficacy of the so-called treatment. The government called on two physicians, both of whom had had extensive experience in dealing with chronic alcoholics and dipsomaniacs. Both physicians testified, of course, that, in their opinion, the so-called Golden Treatment would not cure the liquor habit or cause drunkards to stop the immoderate use of alcoholic beverages, nor would it make any drinker grow to abhor the very sight or odor of liquor, as Goettle had claimed. Furthermore, they testified that this preparation of ginger, red pepper and other substances would not soothe an inflamed stomach or relieve ulcerations, nor would it steady the nerves or restore the vital organs to normal conditions. The physicians naturally brought out the definite relationship between the mental condition of the liquor addict and his addiction. Goettle's lawyer, in cross-examining one of the medical experts who were testifying for the government, endeavored to establish that while the dosage of drugs in the Golden Treatment was less than the recognized "allopathic" dosage, they were homeopathic dosages. The physicians testimony established that the treatment was based upon neither homeopathic nor scientific dosages. Furthermore, as the Solicitor's memorandum brings out, dosages of drugs must be adapted to individual requirements at the time of administration, a fact that Goettle was undoubtedly familiar with if he had investigated the subject to the extent which his attorney's brief indicated. Nevertheless the Golden Treatment was sold in three arbitrarily-fixed strengths to all, without any regard to individual needs.

A brief that Goettle's attorney filed subsequent to the hearing, and which was given due consideration by the Solicitor of the Post Office Department, stated that many testimonials had been received by Goettle from physicians. It appears that some half-dozen letters of this character were submitted at the hearing but perusal of the letters showed that some were

from practitioners who were not physicians but osteopaths or others having little or no training in the use of drugs, and none of the persons apparently was familiar with the formula or the ingredients of the so-called treatment. Still others were evidently anxious to obtain a profit from resale of the treatment to patients. Two of the alleged physicians whose testimonials were submitted were confessed morphine addicts, as well as drunkards. Mr. Crowley states that most of the letters indicated a "serious lack of education on the part of the writers."

Goettle's excuse for producing no witnesses to testify in his behalf was that it was impossible to present medical expert testimony, due to the unwillingness of physicians to testify because, as he put it, they "are fearful of blacklisting and criticism by a certain minority in their profession who profess to act as their brother's keeper." This charge has always been made by fakery in the medical field. While it is certainly a fact that decent medical men will not sell their services to medical fakery, it is also a fact, as unfortunate as it is notorious, that there are a few renegades in the medical profession who can be counted on to testify for a price for even the most notorious of quacks. In discussing Goettle's charge just quoted, the Solicitor for the Post Office Department states that if Haines' Golden Treatment really possessed the merits claimed for it, Goettle would have had no difficulty in getting medical men to testify. Furthermore, Mr. Crowley states that members of the medical profession frequently testify before the fraud order hearings in cases involving medical questions.

Goettle's case consisted chiefly in what purported to be quotations from various medical textbooks, with argumentative interpretations thereof by Goettle's attorney. As Solicitor Crowley pointed out in his memorandum, aside from the fact that Goettle's lawyer was not qualified to interpret such medical texts on a scientific basis, the arguments that were contained in his brief were in many instances based on incomplete and misleading excerpts from the works of medical writers.

The postal authorities are to be commended for having put out of business one of the most despicable forms of fraud in the medical field.

WISCONSIN LAW ON BLOOD TESTS

To the Editor—In March 1935 Governor Lehman signed a bill granting authority to the courts of New York State to order blood tests in certain cases, such as those involving alleged paternity and interchange of babies. A similar bill in the state of Wisconsin, sponsored by myself, passed both houses and was signed by Governor La Follette in August 1935 (758A, chapter 351, Laws of 1935).

My object in this communication is to put on record in the columns of THE JOURNAL certain features of the Wisconsin law that may prove helpful to those interested in sponsoring similar legislation in other states.

In the first place, this bill distinctly states that in cases of disputed paternity the court may order that "the complainant, her child, and the defendant submit to one or more blood tests to determine whether or not the defendant can be excluded as being the father of the child." This makes it clear that the present value of these tests is only to exclude the possibility of paternity rather than to provide positive proof thereof. In order to prevent further the court, jury and district attorney from wrongly interpreting these tests as proof of paternity, the Wisconsin bill states that "the result of the test shall be receivable in evidence but only in cases where definite exclusion is established."

The Wisconsin law allows tests to be made not only by "duly qualified physicians" but also "by other duly qualified persons." Obviously the bacteriologist or serologist most qualified to perform these tests need not necessarily be trained as a physician.

The law provides that "whenever the court orders such blood tests to be taken and one of the parties shall refuse to submit

to such test, such fact shall be disclosed upon the trial unless good cause is shown to the contrary." The significance of this part of the law is quite evident.

The present Wisconsin law makes provision for the use of the blood tests not only in cases in which the state or the community is a party to the action but also in civil actions in which paternity or maternity is in question, for instance, cases in which the problem is to exclude a false claimant to an estate or to detect alleged interchange of babies.

However, no provision yet is made to grant authority to the courts for the use of these tests in criminal cases. This aspect was advisedly omitted since it was felt that successful legislation was more assured with a bill not too involved. Of course, this can be readily corrected by further legislation. The suggestion is here made that workers in other states in framing the proposed bill provide in it also for criminal cases, since in the future a more comprehensive bill is not apt to suffer in its chance for passage, in view of the recent successful legislation in New York and Wisconsin.

Newark, N. J.

BISMUTH IN OIL

To the Editor—In the September issue of the *Journal of the American Pharmaceutical Association* I published an article describing a procedure for evaluating "Bismuth in Oil" preparations and reported in a general way the results obtained on several products. No figures were given nor were the names of any firms mentioned. Recently there has come to my attention an advertisement of the Loeser Laboratory, 22 West Twenty-Sixth Street, New York, in which this article has been reproduced in its entirety, and the implication is made that this is evidence of the superiority of their product. "We offer the following reprint as corroborating evidence of our claim", then follows the article then "It is obvious that in Loeser's Bismuth in Oil a new and higher standard has been established for bismuth suspensions" is part of the language employed.

This article was reproduced without my consent or knowledge and without the consent or knowledge of the editor of the *Journal of the American Pharmaceutical Association*. A vigorous protest on my part brought a profuse apology and a statement that their advertising would be confined to isolated paragraphs. A specimen of this mailed to me still retains all the objectionable features. In fairness to all concerned, and particularly to physicians who may have received an incorrect impression, I wish to make it clear that neither the Maryland State Health Department nor I endorse, by implication or in any other manner, the superiority claims of this firm. On the other hand, we deplore the rather questionable and certainly unethical means employed to further this product.

WILLIAM F. REINDOLLAR, Baltimore
Assistant Chief, Bureau of Chemistry, State
of Maryland Department of Health

GONOCOCCIC TENOSYNOVITIS

To the Editor—In THE JOURNAL, September 28, is an article on "Acute Suppurative Gonococcic Tenosynovitis" by Walter Birnbaum and C. Latimer Callander. In the bibliography no reference is made to the case described by Isadore Zadek in THE JOURNAL of June 15, on "Gonorrheal Tenosynovitis of the Long Head of the Biceps Brachii." Although in the latter case the diagnosis was not made on the pus the tissue examined showed numerous pus cells with intracellular gram-negative biscuit shaped diplococci.

USE OF POISON GAS BY THE U. S. ARMY

To the Editor—In an article entitled "Air Raid Precautions" on page 358 of the August 24 issue of the *British Medical Journal* I note the following statement: "It is notorious too that the U. S. A. favors poison gas as an instrument of warfare considering it not more inhumane than high explosive and constantly using it in cases of civil riot." To the best of my knowledge it is tear gas which is favored for such use as being temporarily incapacitating but nontoxic. It occurs to me that the statement of the American Medical Association to the editors of the *British Medical Journal* might bring about a correction of a misstatement which seems unfortunate. ANNA M. WALLACE, M.D., Elizabeth, N. J.

ANSWER—The assertions quoted from the *British Medical Journal* are incorrect in that they represent that the United States favors poison gas as an instrument of warfare and that the United States uses poison gas in cases of civil riot.

Actually the United States has been obliged to reconcile itself to the likely use of gas in future warfare, following the failure of efforts (in which the United States took prominent part) to proscribe such use by universal agreement.

The use of poison gas in domestic disturbances has never been resorted to within the United States. Chemicals used in riot duty are carefully selected from the group of nonlethal agents. Regrettable misuse of the term "poison gas" results frequently in its application to chloracetophenone and diphenylaminechlorarsine, neither of which is a casualty producer. An attempt to clarify this point was made by the British delegation before the Preparatory Disarmament Commission in 1930, supported by the American representative, Mr. Hugh Gibson, who noted the inconsistency of banning from warfare types of chemicals that were freely and advantageously used in suppressing civil disturbances. However, this attempt by British and American representatives to find a satisfactory solution to a complicated political-technical problem can in no sense be interpreted as committing the United States in favor of the general use of poison gas.

The British Draft Convention, submitted to the General Disarmament Conference, and to which the support of the United States was pledged by President Roosevelt, May 16, 1933, provided for the abolishment of chemical warfare in toto.

PARKINSONISM AND DIABETES

To the Editor—In the early part of 1929 I detected that I had sugar in the urine 10 per cent. I immediately put myself under a very strict diet and high dosage of insulin using sometimes 60 units once a day. Within about a month the sugar and acetone disappeared; however, I continued the treatment for about seven months. Since then I have kept the sugar under control on a moderate diet and the periodic use of insulin. Insidiously with the sugar, a nervous condition in my left foot and arm gradually and imperceptibly crept along such as paresthesia in the left foot, edema in the left ankle and dull pain in the left arm, together with a labored movement, heaviness and slow execution in the movements in these limbs. On exertion and effort there is a tremor; there is also muscular pain and stiffness. I attributed this to the sugar neuritis and muscular rheumatism. Recently I have consulted some specialists on nervous diseases. They made the diagnosis of parkinsonism (not Parkinson's disease). What is the etiology of parkinsonism? Is there any relation in the causative factor of sugar and parkinsonism or is the relation merely incidental in my case? Has a severe strict diet or the continued high dosage of insulin anything to do with parkinsonism? What is the difference between Parkinson's disease and parkinsonism? What is the best line of treatment in parkinsonism? Is hormone therapy of any use? M. D. Egypt

ANSWER—Parkinson's disease (paralysis agitans) may be defined as a chronic progressive disease of the central nervous system, characterized by muscular rigidity, weakness, slowness of movement, and rhythmic, spontaneous tremor. This seldom occurs before the fiftieth year of age and, while no definite pathologic changes have been established, it is believed to be due to degenerative vascular changes affecting the lenticular nucleus.

Parkinsonism refers to a similar syndrome, which may occur at younger age periods and which is due to other causes. The description is consistent with this diagnosis. There are no treatises confined to this subject, but there is a large body of literature on epidemic encephalitis and carbon monoxide poisoning, both of which may be followed by parkinsonism.

There is no established relationship between diabetes and parkinsonism, although, in view of the newer work on the relation

of the hypophysis to diabetes, it might be worth while seeking for a common cause that might affect the nervous ganglions and this gland. It does not seem likely that either the strict diet or insulin dosage could have anything to do with parkinsonism. No hormone therapy for parkinsonism is known. The usual treatment is entirely symptomatic. The tinctures of hyoscyamus, stramonium or scopolamine are frequently employed, as well as calcium and parathyroid.

STREPTOCOCCIC PNEUMONIA

To the Editor—A physician aged 42 was taken ill April 19 while making a call. He had a chill followed by a temperature of 103 F and pain of the lower lobe of the left lung with coughing and expectoration of blood stained mucus. He continued to grow worse. There were daily chills, severe sweats and an increase in temperature with signs of cyanosis. Pain of the lower lobe of the left lung continued with pain more severe over the heart. I was called to see him on the afternoon of April 21. Examination of the chest showed consolidation of the left lower lobe with a spreading of infection into the bronchial tubes and the left and right lungs. The pulse was 108, the temperature was 101, and respirations numbered 24. At this time he had not had his daily chill with increase in temperature. Blood and sputum cultures were positive for *Streptococcus viridans* and a hemolytic staphylococcus infection. No pneumococcus was found. Examinations were made by the state laboratory. Each afternoon between 2 and 4 the patient would have a severe chill, increase in temperature and an attack with pain over the heart and cyanosis. The cough and expectoration of blood and mucus continued to grow worse. On the night of April 22 all treatment was discontinued and he was placed in an oxygen tent sent out by the Ohio Chemical Company. A mixture of oxygen 93 per cent and carbon dioxide 7 per cent was given for ten hours. From this time he was given a mixture of straight oxygen 12 liters a minute and morphine for pain and showed some improvement. In addition to this I advised 1,000 cc of 10 per cent dextrose and physiologic solution of sodium chloride intravenously daily and a blood transfusion if the infection continued to spread. White blood count April 23 showed 17,500 polymorphonuclears, 90 per cent, temperature 97.6. He died on the morning of the 26th following acute dilatation of the stomach. He received only 1,500 cc of dextrose and saline solution. He did not receive a blood transfusion. Please advise me as we are having a sporadic epidemic of this type of pneumonia here. Would you have advised a blood transfusion? If so how soon after the diagnosis was made? Would you have advised daily 1,000 cc of dextrose and saline solution intravenously? If so how soon? Would you have advised some form of streptococcus serum or a nonspecific serum? What other treatment would you have advised in addition to the foregoing if any? Please omit name.

M D Alabama

ANSWER.—Obviously the patient had an overwhelming streptococcal pneumonia with bacteremia. It is unlikely that it would have terminated favorably as a result of any known type of management. There is no known serum or vaccine available the use of which would have materially influenced the outcome. The prompt administration of oxygen is to be commended. To place the patient in an atmosphere supersaturated with oxygen (from 60 to 70 per cent), preferably by means of an oxygen chamber, but lacking that, an oxygen tent carefully adjusted, or the nasal catheter method, is the most effective clinical procedure available. Morphine is indispensable. Intravenous dextrose solution, from 5 to 10 per cent, given slowly, may well be administered daily in amounts of from 1,000 to 2,000 cc unless contraindicated. Continuous gastric siphonage and blood letting are frequently of great benefit in acute pneumonia. Blood transfusions would probably be of little avail in an acute overwhelming pneumonia, such as is related in this case, and is probably not to be recommended. The use of nonspecific serums and vaccines in acute pneumonia is a question not settled as yet. There are those who enthusiastically recommend and use them, citing prompt temporary and occasionally permanent remissions in clinical manifestations. In a pinch, lacking other means better supported by clinical observation, such procedures may be and often are used. There can be no criticism of so doing when employed under such circumstances.

TREATMENT OF STERILITY

To the Editor—Two young married women have been married several years and have never been pregnant. Both are anxious to have children. One of them has a decided acid vaginal secretion which I am trying to neutralize partly. There is no history of tubal inflammation and they are as passionate as the normal woman. Is there anything in the realm of glandular therapy that would help them? I get a bewildering number of pamphlets extolling the different products. If there is anything worthy of trial will you kindly let me know? Please omit name.

M D West Virginia.

ANSWER.—The answer to these questions is not to be found in the advertisements of pharmaceutical concerns but may be revealed after a thorough investigation of the matings in question. A scientific inquiry into the fecundity of each partner and the performance of accepted tests for fertility will doubtless uncover the cause or causes of the reproductive failure.

A plan for making such a study of apparently infertile couples will be found in recent books on sterility and in the current literature.

Acidity of the vaginal secretion is the normal reaction and as such requires no treatment.

Glandular therapy may be beneficial to one or the other partner, but a valid indication for its use must first be established. Following are references.

GRATING NOISE IN CERVICAL VERTEBRA

To the Editor—An unmarried white woman aged 42, complains of a grating noise which she believes comes from the region of the upper cervical vertebra and base of the brain. This is noticed particularly when she rotates her head from side to side but does not bother her when she moves her head in the up and down direction. The noise can be heard without the aid of a stethoscope when the examiner places his ear near the occipital and mastoid regions of the head. This noise is much like that which is heard on bending a knee that has long been afflicted with a chronic hypertrophic type of arthritis. The patient dates the beginning of this disturbance back to four years ago following a course of sweat baths for a hypertension. Except for this hypertension which varies from 160 to 190 systolic with a diastolic pressure of 90 mm. of mercury her physical condition is excellent. There is no evidence of any condition of arthritis in any other part of the body and so far as I can ascertain, there are no foci of infection. Anteroposterior and lateral roentgenograms of the cervical spine are negative. This disturbance has become quite an annoyance to the patient and any suggestions you may have to offer in the way of therapy will be greatly appreciated.

HARVEY L JORGENSEN M D Marinette, Wis

ANSWER.—This patient should be treated as though she had arthritis. There are practically always two factors involved in this lesion viz, trauma (either a single severe one or multiple minimal ones), and infection especially of the teeth, throat, sinuses, gastro-intestinal and genito urinary tracts and lymphatic system.

Has her neck ever been treated by an osteopath or chiropractor?

If the condition is sufficiently annoying, the following treatment is outlined:

- 1 Rest on a hard mattress, in a bed with its head elevated from 6 to 8 inches, with
 - 2 Application of head traction
 - 3 Immobilization in a plaster-of-paris cast or a Schrock type of brace, followed by a special collar like the collars of H O Thomas, Schanz or Wallace
 - 4 Physical therapy consisting of radiant heat, massage and either diathermy or short wave diathermy
- Foci of infection and metabolic or endocrine disturbances should be investigated. Vaccine may be considered.

TREATMENT OF AMENORRHEA

To the Editor—A white girl nearly 18 years old has not yet menstruated. She complains of occasional pains in the back, headaches and fatigue. The past history is negative. She weighs 125 pounds (56.7 Kg.), is 5 feet 5 inches (165 cm) tall and is of normal development. The thyroid is not palpable. The blood count is normal. The basal metabolism is normal. What is the cause and what treatment should be given? I have given her four injections of antuitrin S 100 rat units each time. Is it advisable to use theelin simultaneously and for how long a period? Should the dose be gradually increased and in what intervals? Rectal examination does not reveal anything abnormal. Vaginal examination is impossible. Please omit name and address in case of publication.

M D New York.

ANSWER.—Primary amenorrhea is usually difficult to overcome. In some instances menstruation sets in spontaneously, especially in those under 20 years of age. In many cases of amenorrhea, bleeding may be induced by giving huge amounts of estrogenic substance, this may be followed (but not necessarily) by corpus luteum hormone (progestin). However, these bleedings will recur only as long as the former or both hormones are administered. If the hormones are not given, the so called menstrual periods cease. Since ovulation is not produced, there is generally no use in giving this treatment even to married women, because pregnancy cannot possibly be brought about by it. In the case cited undoubtedly the patient has a hypoplastic uterus. While such a uterus can be enlarged by means of hormone therapy and develop a functioning endometrium, it will retrogress as soon as the hormone therapy is stopped. Not infrequently desiccated thyroid is much more helpful in such cases than other hormone therapy.

The only value there is to the bleeding induced by hormones is a psychic one. If women who have amenorrhea are convinced that they are as healthy as women who do menstruate, there is usually no need to treat them for the amenorrhea.

If the physician would like to try hormone therapy he may administer 50,000 international units of estrogenic substance (Amniotin, theelin and so on) on the first, fourth, seventh, tenth and thirteenth day of a course and then give 15 rabbit units of progestin on the seventeenth, eighteenth, nineteenth, twentieth and twenty-first days. If bleeding is to follow, it will usually take place within ten days after the last injection of progestin.

Anterior pituitary-like gonadotropic hormone of the urine of pregnant women may be administered in place of progestin, but it is doubtful whether the result obtained is equivalent. This hormone should be injected intramuscularly in doses of from 150 to 200 rat units daily for five or six injections. In order to produce successive periods of bleeding, these courses of treatment will have to be repeated.

ARTHRITIC ANKLE

To the Editor—A man aged 74 married came to me with the complaint of aching ankle joints of about three months duration aggravated by walking but present during rest as well. The ache or a weakness in the ankles is localized in the ankle joints. Examination of the feet did not disclose anything significant. The dorsalis pedis and posterior tibial arteries were palpable; there was no cyanosis or trophic changes of any kind. There was no evidence of arthritic changes; the motion of the joint was unimpeded and no crepitus was elicited. The longitudinal and transverse arches were apparently normal. He used arch supports owing to the fact that his occupation necessitates his standing nearly all day. The general physical examination revealed a blood pressure of 180 systolic 88 diastolic, temperature 98.2 F, pulse 50, respirations 18. His hearing was impaired. The tympanic membrane showed retraction and there was distortion of a cone of light. The pupils were equal and regular and reacted to light and in accommodation. Examination of the fundus revealed tortuosity and irregularity of the caliber of the vessels. The teeth were all removed and supplanted by plates. The tonsils were atrophic. The sinuses were apparently normal by transillumination. The lungs were essentially normal. The heart was enlarged downward and outward and auscultation revealed accentuation of the second pulmonary sound. No murmurs were noted; the rhythm was normal except for occasional extrasystoles and the slow rate already noted. The abdomen was essentially normal as were the reflexes. Undoubtedly the patient's occupation has much if not everything to do with his complaint. For economic reasons he cannot give up his work. He has consulted several physicians in the last few months without relief. Besides the arch support that he is using at present he has used for longer or shorter intervals ankle supports, diathermy and strapping. Roentgenograms which I have not seen have not revealed any pathologic changes in the involved joints. Your comments and suggestions for further treatment would be greatly appreciated.

S J Wojcik M D Paw Paw Ill

ANSWER—While the lesion seems to be in the ankle joint proper it may be in the subastragal joint. One may have an arthritic joint without positive pathologic changes in the roentgenogram.

The patient's weight is not stated, nor is mention made of the basal metabolic rate or his dietary habits.

The various factors that have to be eliminated in this case are mechanical, circulatory, traumatic, infectious, myogenic, neurogenic, metabolic and endocrine. The chief traumatic factors may be occupational.

A few days of absolute rest in bed with the application of an anodyne lotion and fomentations may be helpful. Proper high laced shoes and resilient supports with a slightly raised inner heel border may be all that is required to give the man comfort. In addition, massage and contrast sprays should improve the circulation. If unsuccessful, a plaster cast and crutches for a short period would be indicated.

MULTIPLE SCLEROSIS

To the Editor—What is the latest treatment for multiple sclerosis? Sodium cacodylate, quinine and injection of whole blood intramuscularly were used with no evidence of benefit.

M D, Michigan

ANSWER—The latest treatment for multiple sclerosis remains as yet empirical. Any disease that has spontaneous remissions usually boasts of multiple and variegated types of treatment. In a number of cases, remissions do not occur at all. The following is suggested: Absolute bed rest for a period of from six to ten weeks for an acute case, this rest includes no reading. During the chronic period abstention from all forms of severe exercise together with solution of potassium arsenite in doses of from 0.2 to 0.6 cc three times a day nearsphenamine intravenously once a week or quinine hydrochloride starting with 0.03 Gm three times a day, gradually increased until about 0.3 Gm three times a day is taken. For acute retrobulbar neuritis, in addition to absolute rest one should give foreign

protein intravenously (typhoid paratyphoid) for at least six or seven injections. The most important part of any regimen in the management of a case of multiple sclerosis is absolute rest and more rest.

COMPLICATIONS IN PNEUMONIA

To the Editor—Please inform me as to the proper treatment of the following complications in an otherwise typical case of lobar pneumonia. A toxic hepatitis (manifested by persistent and gradually increasing jaundice of skin and sclerae, stupor and other nervous manifestations accompanying jaundice). The liver apparently not enlarged or tender to palpation. Persistent exhausting and uncontrollable hiccups. The patient died but the heart and circulation remained good almost to the end. Several years ago I am informed by the patient's relatives the patient had a rather severe case of malaria. Do you think that the malaria could have so injured the liver that it failed to function normally when obliged to take care of the toxin due to the pneumonia? In other words, how much of a part would malaria play as an etiologic factor in the causation of a toxic hepatitis accompanying lobar pneumonia? Dextrose intravenously was given every day once a day 50 cc of concentrated solution and toward the last three or four times a day. Please omit name and address.

M D North Carolina

ANSWER—Jaundice is not a rare complication in pneumonia especially in severe infections. In the case described the toxic hepatitis and stupor strongly suggest pneumococcal bacteremia, a frequent finding in fatal cases of pneumonia. The hiccups may have been another expression of severe toxemia or possibly the result of diaphragmatic irritation (diaphragmatic pleurisy). It is doubtful whether the attack of malaria several years before the pneumonia played any part in the development of the jaundice.

TREATMENT OF LATENT SYPHILIS

To the Editor—What plan of treatment would you advise for a 53 year old patient with a 4 plus Wassermann reaction (during a routine test) with no symptoms or physical anomalies? He has had no treatment whatever and the history of infection dates back eighteen years. Kindly omit name and address.

M D Chicago

ANSWER—In the absence of definite signs of cardiovascular disease or neurosyphilis, the case may be treated as one of latent or asymptomatic syphilis. The patient should receive alternating courses of one of the arsphenamines intravenously and an insoluble bismuth compound intramuscularly with iodides between courses. Treatment should be continued with short periods of rest for at least a year and then intermittently until the positive reaction is reversed.

VENT DISEASE OF RABBITS

To the Editor—Can you tell me what vent disease is in a rabbit? It is communicable from male to female and vice versa and is characterized by excoriated genitalia and a discharge green in character. Is the micro organism known? What can be done to treat it?

EDWARD N TURKUS M D Long Beach Calif

ANSWER—Vent disease, or treponemiasis, is caused by the spirochete *Treponema cuniculi*. This organism is regularly transmitted through the process of breeding from male to female and vice versa. In commercial rabbitries where valuable breeding animals are maintained detailed systematic treatment may be justified. Local applications on the genitalia of a 2 per cent solution of copper sulphate, zinc ointment, or mercurial ointment is recommended. The use of nearsphenamine for subcutaneous injection in doses varying from 0.05 to 0.15 Gm, according to the size of the animal may result in a permanent cure if used in conjunction with local applications. Apparently the same line of treatment as is used for the treatment of syphilis in human beings is effective, but recovery may be expected in a shorter time. In ordinary rabbits used for laboratory experimental work such procedures are not justifiable, and it is more economical to dispose of the affected stock and after a thorough cleansing and disinfection of the hutches to replace them with healthy animals.

FORMULA FOR ECZEMA OF AUDITORY CANAL

To the Editor—On page 496 (February 9) of THE JOURNAL is the following formula for the treatment of eczema of the auditory canal.

| | |
|-------------------|--------------------------|
| Oil of birch tar | 0.8 cc |
| Resorcinol | 0.4 cc |
| Liquid petrolatum | sufficient to make 16 cc |

Our druggist states that he has tried to mix this but that the tar and the resorcinol will not go into solution. Can you advise?

M D Minnesota

ANSWER—An expert pharmacologist has wrestled with this problem and says that the only method he can suggest is to dissolve resorcinol 0.4 Gm in glycerin 5 cc, dissolve the oil of birch tar 0.8 cc in liquid petrolatum 11 cc, then mix the two solutions, and label them "Shake well immediately before using."

BURNING PAIN DURING INTERCOURSE

To the Editor—A man aged 55, in perfect health as far as I can find out lives on a farm. He is 5 feet 11 inches (180 cm) tall and weighs 200 pounds (90 Kg). The heart and lungs are normal. The teeth are very bad. The blood pressure is 115 systolic, 60 diastolic. The Wassermann reaction is negative. The blood count is normal. The kidneys are normal. Urinalysis gives negative results. He has some lancinating pains in the lower limbs and vitiligo of the dorsal surface of both hands. He states that during sexual intercourse the semen burns like a red hot poker and if a drop of it touches his wife anywhere on the vaginal mucous membrane it burns her just like fire. I would be glad to know the cause of this if possible. Please omit name.

M D, Illinois

ANSWER—Burning pain during ejaculation is not a rare condition and is generally due either to an intense congestion of the prostatic urethra or to ulcerations or granulations or similar pathologic conditions in that region. Treatment consists in getting rid of the pathologic condition, which is usually accomplished by gentle prostatic massage and instillations of weak (from 1,300 to 1,500) silver nitrate solutions into the prostatic urethra with the Bangs sound syringe.

There is no condition of the ejaculatory fluid that could possibly cause any burning when brought in contact with the vaginal mucous membranes. There may of course be present an intense vaginitis or increased sensibility of the vaginal mucous membrane, but, what is more likely, the symptoms in the wife are either psychic or suggestive.

DEAFNESS AFTER TETANUS ANTITOXINS

To the Editor—A patient became deaf after receiving tetanus antitoxin. Can tetanus or tetanus antitoxin cause deafness? Kindly do not use my name.

M D Michigan

ANSWER—A moderately extensive but not exhaustive search of sources of information does not disclose any report in which deafness has been caused by tetanus. Optic neuritis and peripheral neuritis have been noted as occasional complications, and it would accordingly appear not impossible for deafness also to occur after tetanus.

Other possibilities must be considered. Tetanus may occur in a patient who already has auditory changes that have escaped notice of the patient previous to his acute illness. Coexistent disease of the central nervous system, such as cerebrospinal syphilis, also must be considered.

Serum disease frequently follows the injection of foreign serum, especially when large doses, usually required in tetanus, are used. Urticaria as well as hemorrhages in various parts of the body, including joints and internal organs, are frequent, and if such a lesion occurred in the ear, deafness either temporary or permanent might result.

EFFECTS OF SCARLET FEVER TOXIN WHEN SWALLOWED

To the Editor—A physician's son aged 6 years was discovered by his mother playing with a box containing 100 vials of Squibb's scarlet fever toxin. She suspects that the vials were full of solution originally but has no way of being sure. If the child did swallow the contents of all or part of these vials what may develop and what would you suggest? Please omit name.

M D, Vermont.

ANSWER—If the child was previously susceptible to scarlet fever and swallowed such an amount of toxin he has partially or completely immunized himself against the disease. It will do no harm. No treatment is indicated.

EFFECTS OF AMYTAL

To the Editor—Please tell me whether the prolonged use of sodium amytal from 12 to 15 grains (0.8 to 1 Gm) daily, (1) has a cumulative toxic effect (2) affects the eyes (3) results in a habit formation that is difficult to break or (4) is apt to cause skin manifestations. Please omit name.

M D New York.

- ANSWER—1 It may have.
2 There is apt to be dilatation of the pupil.
3 Yes.
4 It is.

LIGHT RAYS IN TUBERCULOSIS

To the Editor—Are actinic rays artificially produced (such as those generated by a quartz burner of the Hanovia Chemical Company) contra indicated in pulmonary tuberculosis? Would a gradual tanning of the skin of the chest be detrimental or beneficial?

J PHILLIPS EDMUNDSON M D Kansas City Mo

ANSWER—No it is not contraindicated but found to be of no value and may do harm in overdosage.

Gradual tanning of the skin of the chest would have no action at all either detrimental or beneficial.

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Written examination for Group B applicants will be held in various cities throughout the country March 14. Oral examination for Group A and B applicants will be held in Kansas City Mo. May 11-12. Applications for written examination should be filed with the secretary before Jan 15. Sec. Dr. C. Guy Lane 416 Marlboro St. Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada Dec. 7. Applications must be filed not later than Nov. 1. Sec. Dr. Paul Titus 1015 Highland Bldg. Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY St. Louis Nov. 18. Asst. Sec. Dr. Thomas D. Allen 122 S. Michigan Ave. Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St. Louis Jan. Sec. Dr. Fremont A. Chandler 180 N. Michigan Ave. Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY Kansas City Mo. May 9. Sec. Dr. W. P. Wherry 1500 Medical Arts Bldg. Omaha.

AMERICAN BOARD OF PEDIATRICS St. Louis Nov. 20. Sec. Dr. C. A. Aldrich 723 Elm St. Winnetka Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY New York Dec. 30. Sec. Dr. Walter Freeman 1726 Eye St. N. W. Washington D. C.

AMERICAN BOARD OF RADIOLOGY Detroit Dec. 12. Sec. Dr. Byrl R. Kirklin Mayo Clinic Rochester Minn.

Book Notices

Diseases of the Thyroid Gland. By Arthur E Hertzler M.D. Professor of Surgery University of Kansas. With a chapter on Hospital Management of Goiter Patients by Victor E Chesky M.D. Chief Resident Surgeon Halstead Hospital. Third edition. Cloth. Price, \$7.50. Pp. 348 with 181 illustrations. St. Louis: C. V. Mosby Company 1935.

This book includes chapters under the classifications of etiology, normal morphology, goiter in childhood, nontoxic colloid goiter, toxic colloid goiter, toxic diffuse goiter, atypical toxic goiter, degenerating goiter and constitutional effects, tumors of the thyroid gland, goiters in unusual places, thyroiditis, hypothyroidism, hospital management, topographic anatomy and surgical technic. Hertzler begins with a premise that goiter is a lifetime disease, which, "once fully established," when persisting beyond adolescence or resisting medical treatment, does not afterward regress. His statements that the thyroid is "pretty much a useless organ and may be cast aside with advancing age" and that severe hypothyroidism, following complete removal, occurs only in adolescents and not adults" are open to serious argument. True it is that a number of surgeons with extensive experience with goiter prefer a definite postoperative hypothyroidism to a mild hyperthyroidism, because of the danger of secondary surgery for residual hyperthyroidism, basing their contention on the fact that it is easier to feed thyroid than to dissect a definite scar for tiny thyroid remnants. Nevertheless the present conception of adequate removal of toxic goiter is becoming more and more radical—that there is a tendency to leave less and less thyroid tissue after operation. Individual chapters devoted to nontoxic colloid goiter, goiter in childhood, toxic diffuse goiter and atypical toxic goiter are excellently presented as to pathology and symptomatology. One gets the feeling that the author has "surgical intentions" toward every goiter, colloid or otherwise, persisting beyond childhood. However, reading closely, one finds such a balancing statement as this: "The majority of operative failures come from trying to cure family rows by removing a simple colloid goiter." In proportion to the detailed thoroughness of the remainder of the book, the chapter on technic is rather thin. On the other hand no one will ever learn thyroid surgery from a book or at all. The uniform use of local anesthesia for toxic goiter is not a

generally accepted procedure, even though in Hertzler's clinic the surgeons here wear no mask, but they keep their mouths shut." In general the technic described and illustrated is that practiced by most goiter surgeons. Barring such criticisms as those here outlined, which after all represent merely a difference of opinion, this textbook represents a noteworthy contribution to surgery of the thyroid gland.

Précis de thérapeutique et de pharmacologie. Par A. Richaud et R. Hazard. Préface de A. Desgrez. Seventh edition revised by R. Hazard. professeur agrégé à la Faculté de médecine de Paris. Cloth. Price 100 francs. Pp. 1257 with 34 illustrations. Paris: Masson & Cie 1935.

It is a pleasure to see a book on this subject come from the institution where François Magendie and Claude Bernard did so much for experimental pharmacology and medicine. Since their time however, pharmacology in France has been in a great depression. Professor Richaud died some time ago and by his own wish the work of revision fell to Professor Hazard. In a short preface Professor Desgrez points out that since the appearance of the sixth edition ten years ago the advance in synthetic chemistry, chemical therapy, serotherapy, vaccine therapy, vitamins and general pharmacology makes such a revision necessary.

The task of renovating an old book, and especially one that has been successful is difficult indeed. It is extremely difficult for a pharmacist to discard drugs that have long been and that are still prescribed, although critical work may have shown their use questionable or worthless. Consequently this book, while it adopts the new hesitates to bury the dead. This is a universal failure in textbooks of pharmacology and therapeutics. As a "precis" it is quite large. The subject matter is divided into three parts. Part I is devoted to general pharmacology and occupies about one fourth of the whole. Part II is devoted to special pharmacology and occupies 845 pages. This is subdivided into (1) inorganic drugs, (2) synthetic organic chemicals, (3) products of vegetable origin, and (4) products of animal origin. Part III deals briefly with pharmacy, the prescription, dosage and allied subjects.

The general pharmacology is too brief to be considered adequate in our best medical schools. However, it is supplemented to a large extent in the special part, and the whole is satisfactory. There are no original tracings, but instead a few diagrammatic representations. This perhaps is not a drawback, since it is not the tracings per se but a knowledge of how they are obtained and individual work in obtaining them that is most valuable to the student. In a book of this size, one might expect some references to the original literature but there are none. Instead, a few names are mentioned. The authors explain this omission on the ground that it often is difficult to determine the paternity of an experimental fact or discovery.

In part II the method of discussion may be illustrated by mentioning a few of the important drugs. The discussion of iodine occupies twenty pages, covering its preparation characteristics, reactions, occurrence in nature, in water, in air, in sea water, in vegetables, in animals, under physiologic effects, its local action, general action and therapeutic applications and preparations. Ergot is disposed of in two pages. While digitalis gets nine, opium and its alkaloids occupy twenty-seven pages. Some of the work of the last two years is not mentioned, e. g., copper in hemoglobin formation or the excretion of morphine, but from a practical point of view the omissions are neither numerous nor serious.

Part III which discusses the pharmacy and prescription writing, strikes one as being somewhat backward, modern prescription writing emphasizes simplicity, and, while Professor Hazard is in the main conservative he gives an example of the complete prescription, which includes a base, an adjuvant, a corrective, a corrective adjuvant, an intermediate and an excipient. While he hastens to say that these are not always used, it is not sufficient. Such mixtures are unscientific, unnecessary and often detrimental. Worse still, they disorient and confuse the student, often beyond recovery in the time devoted to the subject. If they are mentioned at all, it should be to condemn them.

The book as a whole contains the essentials of pharmacology and therapeutics but is weak in pharmacology and contains an excessive number of drugs or therapeutics, many more than are needed. An excessive number paves the way to weakness in therapeutics. It is no condemnation to say that English

speaking people would gain little by a translation of this book. It can be recommended, however, to students and others who wish practice in reading French and who wish to get a view of French pharmacology and therapeutics at first hand.

Abnormal Arterial Tension By Edward J. Stieglitz M.S. M.D. F.A.C.P. Assistant Clinical Professor of Medicine Rush Medical College of the University of Chicago. Edited by Morris Fishbein M.D. Cloth Price \$4 Pp 261 with 66 illustrations. New York: National Medical Book Company Inc. Doubleday Doran 1935.

In this little volume the author succeeds in covering a good deal of ground, even if he does not go into considerable detail. He discusses the methods of taking blood pressure measurements and their symptoms. The factors that alter blood pressure within normal variations and cause elevation or depression are considered fairly well under various headings. It is interesting to note that in the discussion of the symptoms of hypertension the author classifies them as cardiac, neurologic and renal. He succeeds fairly well in giving an acceptable description of the subject. Coronary sclerosis he considers as part of chronic hypertension. Under the subject of acute hypotension the author has an opportunity to describe the condition of shock. The states of chronic hypotension, as Addison's disease and those resulting from disturbed nutritional states or chronic infections, are given some space. The subjects of prognosis and treatment are fairly good. There are many illustrations, charts, diagrams and reproductions of roentgenograms. This book can be recommended highly to the general practitioner and student.

Die Haut und Geschlechtskrankheiten Eine zusammenfassende Darstellung für die Praxis Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Lieferung 21/22. Band II. Hautkrankheiten entzündlicher Natur I. Teil. Von Prof. Dr. Gabor Nobl. Hautkrankheiten entzündlicher Natur II. Teil. Von Prof. Dr. Oscar Niggel. Hautkrankheiten entzündlicher vorwiegend beruflicher Natur und ihre Stigmata. Von Priv. Doz. Dr. Alfred Perutz. Paper. Price 16 marks. Pp 235. 540 with 173 illustrations. Berlin and Vienna: Urban & Schwarzenberg 1935.

Die Haut und Geschlechtskrankheiten Eine zusammenfassende Darstellung für die Praxis Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Lieferung 23/24. Band II. Die Hypertrophien der Epidermis. Von Prof. Dr. M. Oppenheim. Die Hypertrophien des Pigmentes. Von Prof. Dr. M. Oppenheim. Blindegebebi hypertrophien. Pachydermien. Von Prof. Dr. Eduard Neuber. Atrophien. Von Priv. Doz. Dr. Stefan Robert Brünauer. Neurosen der Haut. Von Priv. Doz. Dr. Alfred Perutz. Paper. Price 18 marks. Pp 541. 828 with 95 illustrations. Berlin and Vienna: Urban & Schwarzenberg 1935.

In the volume devoted to a consideration of the inflammatory dermatoses are included chapters on the toxic erythemas, urticaria, prurigo, neurodermitis and the varicose symptom complex, a section on the papulosquamous dermatoses, and a thorough discussion of industrial dermatoses. Discussion of these subjects is detailed and well organized and is greatly aided by the liberal use of excellent reproductions of photographs in black and white and plates of moulages in colors.

The same thoroughness of discussion marks the volume devoted to a consideration of the hypertrophies and atrophies of the skin and pigment and to the cutaneous neuroses. The numerous illustrations tend to make these volumes a veritable atlas. While the books are obviously intended for the specialist in this field, the readability of the text and the excellence of the illustrations make them a valuable source of information for all physicians.

Dial Away Your Fat. Vest Pocket Calorie Calculator Does It! Paper. Price 25 cents. Pp 32. Los Angeles: The Health Builders 1935.

This pocket-size booklet consists essentially of a series of alphabetically arranged and indexed tables of 100 calorie portions of foods. It derives its name from a dial, attached to the front cover, with which the user is able to keep a tally of the number of calories eaten during the day. Space is provided in the back of the booklet for recording the daily total caloric intake and the daily weight. The tables are preceded by a brief discussion of the principles of weight reduction and a criticism of some commercially exploited nostrums. An initial diet of from 1,200 to 1,400 calories is advised followed by an increase "if you are losing weight too rapidly" until "the weight loss is satisfactory." The booklet is an honest attempt to extract a profit from the obesity problem. The problem is properly presented as a balance between energy intake and energy expenditure and the information is sold as such and not as an inert powder or bath salt.

The ready reference and recording features are commendable. However, this commercial venture is subject to the same serious objections as all similar projects. It assumes that the individual who attempts to use it will be normal except for overweight, and that he or she is capable of adjusting the diet both qualitatively and quantitatively so as to avoid the injurious effects of improper dieting. The experienced physician knows that these assumptions are not valid in a large percentage of cases. These booklets would have a much greater claim for recommendation if distributed only through physicians in conjunction with proper medical supervision.

Kings and Some Kings Men Being a Record of The Medical Department of King's College London from 1830 to 1909 and of King's College Hospital Medical School from 1909 to 1934 By H. Willoughby Lyle M.D. F.R.C.S. Fellow of King's College London Consulting Ophthalmic Surgeon to King's College Hospital. Cloth Price \$9. Pp 613 with 18 illustrations. New York & London: Oxford University Press 1935.

This is a delightfully written account of the alma mater of many of the medical giants, past and present, in the British empire. To lovers of tradition this intimate narrative of steady progress, honest effort and scientific achievement should prove most instructive and illuminating. "Traditions," writes the author, "are made up chiefly of unwritten doctrines, customs, practices, and the endeavors of those who have 'gone before' and are transmitted from one generation to another. Traditions are in all probability the most valuable assets which a medical school and hospital possess, and they impart to it a personality which goes to make both respected and even beloved." In the United States the Massachusetts General Hospital, Boston, can point to such love and veneration for tradition. Lord Lister, Watson, Cheyne, Lenthal Cheatle, Thomas Percy Legg and Hutchinson Roy Bell are names familiar to all who can truly call themselves surgeons in the United States. The list of internists and other specialists is equally imposing. Many amusing incidents and anecdotes of more than local interest are recounted, among them the uncalled for antagonisms on the part of members of the nursing staff who objected to Lord Lister's operating on a young boy for acute osteomyelitis of the leg and sought forcibly to prevent the patient's being carried from the ward to the operating room. Also significant is the fact that Lister would accept the chair of surgery at King's only on condition that four men whom he had trained in Edinburgh be allowed to come with him. One learns that Cheyne became a surgeon-rear-admiral during the World War, that hundreds of King's graduates served their country, fifteen of them being killed in action. Of purely "alma mater" interest are the histories of the various King's clubs and societies, from cricket to tennis, but their achievements make one realize how close a corporation was this combination of school and hospital. A list of the teaching staffs, medical associates, scholarships and prizes won by King's men and an excellent index complete the volume. One of the illustrations shows King's College Hospital as it was in the year 1839.

Diseases of the Nervous System A Text Book of Neurology and Psychiatry By Smith Ely Jelliffe M.D. Ph.D. and William A. White M.D. Superintendent of St. Elizabeth's Hospital Washington D.C. Sixth edition. Cloth Price \$9.50. Pp 1175 with 510 illustrations. Philadelphia: Lea & Febiger 1935.

This is the most modern and thorough textbook of its kind. In addition to having all the good qualities of the preceding edition, the present one may rightly boast of containing descriptions of the most recent methods and tests and discussions of present-day thought and investigations in relation to neuropsychiatry and general medicine. The specific changes made in addition to the careful revision of the entire work are the addition of new methods of examination, recent metabolic studies in relation to the pathways of the hypothalamus, surgery of the sympathetic nervous system, an entirely new chapter on the endocrine entities, revision of the chapter on spinal cord lesions, addition of some of the less common peduncular and midbrain lesions, new thoughts in cerebral neoplastic localization, and considerable addition of new material to the psychic or symbolic systems with explanatory interpretation of what one finds in these various psychic entities. There is a good bibliography, and the illustrations are excellent. The text and the printed type are easy to read. This book is highly recommended for use by students, practitioners and neuropsychiatrists.

Commoner Diseases of the Skin By S. William Becker M.S. M.D. Associate Professor of Dermatology School of Medicine, University of Chicago. Edited by Morris Fishbein M.D. Cloth. Price \$4. Pp. 283 with 83 illustrations. New York: National Medical Book Company Inc. Doubleday Doran & Co. 1935.

This book presents, in lecture style, full discussions of the more common skin diseases. Underlying principles are emphasized so that, while not encyclopedic in the sense of a textbook, it covers the field of general dermatology fairly well. The physiologic and biologic approach is used in describing the etiology. The field of allergy is related to the skin is well covered and up to date. The chapters on the neurodermatoses and pigmentary dermatoses of the skin are especially good. In treating neurodermatoses, the author has stressed the necessity of treating the nervous exhaustion that occurs so frequently in patients suffering from this disease. The treatment of certain forms of dermatoses are illustrated by case histories. The photographic illustrations are excellent and well selected in connection with the text. The author has limited the therapy to one or two well chosen and accepted forms of treatment for each disease. There is also a separate chapter devoted to pharmaceutical details and prescriptions. The value of psychotherapeutic measures in dermatology is discussed. The volume covers the field of dermatology adequately for the general practitioner and student.

Medicolegal

Workmen's Compensation Acts Physician's Right to Initiate Proceedings Before Industrial Board—Medical treatment to an injured employee was rendered by Dr. Meherin, on authorization of the employer. Later, being unable to collect his fees, Dr. Meherin filed an original application with the industrial accident commission of California, naming himself as applicant and the injured employee and his employer and its insurance carrier as defendants and asking an adjustment of his claim. A hearing was had on the application, at which the employee did not appear. Subsequently, at the invitation of the referee, he joined in the proceedings and submitted his claim on the record as it then stood. Thereupon the commission awarded him compensation and included in it an award for medical treatment, payable directly to Dr. Meherin. The state insurance commissioner, as liquidator of the insurance carrier, petitioned the Supreme Court of California for a review and annulment of the award.

The chief objection to the award was based on the facts that the original application for adjustment of the claim was filed not by the injured employee but by Dr. Meherin, and that within the time limited by the statute no proper application was filed by either the employer or the employee. There can be no question, said the Supreme Court, that if Dr. Meherin was not entitled to file the application, no proper application was timely filed and the whole award must be annulled. On the other hand, if Dr. Meherin was entitled to file the original application the employee could be brought in by the industrial accident commission at any time during which the commission had continuing jurisdiction and was entitled to the same consideration as if he had initiated the proceedings. The physician in this case named as defendants all parties having any possible interest in the subject matter. In effect, he filed an application not alone for himself but also on behalf of the injured employee. The basis of the proceeding was not an alleged independent right of the physician against the employer but the liability of the employer to the employee, to which the incidental liability of the employer to the physician was a necessary concomitant. If the employee was properly a party to the proceeding, said the court, no difficulty arose with reference to making an award in his favor and impressing thereon a lien in favor of the physician.

The workmen's compensation act of California authorizes the filing of an application by any party in interest. Although a physician's right to payment for medical services is incidental to the employee's right to compensation, concluded the court, nevertheless a physician who has rendered medical services to an injured employee has an interest in the subject matter of the controversy sufficient to bring him within the class design-

nated by the act as "parties in interest" who may file an application. The award of the industrial commission was consequently affirmed.—*Independence Indemnity Co. v. Industrial Accident Commission (Calif.)*, 41 P. (2d) 320, *Same*, 41 P. (2d) 327.

Malpractice Needle Left in Abdomen—Sugaya was referred by his attending physician to the physician-defendant for an appendectomy. At operation the appendix was found to be perforated and was removed. The incision was closed, except where provision was made for drainage. The physician-defendant attended the patient during the critical period following the operation. Thereafter the attending physician managed the case and made the necessary changes in the surgical dressings. About three and one half months after the appendectomy a straight needle was located in the abdomen by roentgenograms and was surgically removed from the psoas muscle by a third physician. The patient then sued the physician-defendant. From a judgment of the trial court in favor of the patient the physician defendant appealed to the district court of appeal, first district, division 2, California.

The only question to be decided, said the district court of appeal, is whether the indirect evidence, in the absence of direct evidence, was sufficient proof that the needle removed from the patient's psoas muscle entered the patient's abdomen during the appendectomy. A medical witness testified that the needle might have arrived at the location from which it was removed (1) through swallowing, (2) during the operation or (3) during the after-treatment by the attending physician. The patient testified that to his knowledge he had not swallowed the needle nor had he had a previous operation. The attending physician testified that he used no needle in the treatment after the operation. And the physician-defendant testified that, while straight needles were carried on the nurse's tray during the operation, he himself had used only curved needles. Assuming this testimony to be true, said the court, then the needle must have arrived in the patient's abdomen through inadvertence and without any actual knowledge on the part of any one. The only time when needles similar to the one described in the evidence were in close proximity to the patient's abdomen was during the operation. The jury could properly conclude, said the court, that it was more probable that the needle entered the abdomen through inadvertence during the operation and while the wound was fully open than at any time before or after. The judgment of the trial court in favor of the patient was affirmed.—*Sugaya v. Morton (Calif.)*, 40 P. (2d) 581.

Typhoid Fever Liability of Municipality for Typhoid Fever Contracted from Municipal Water Supply—The defendant city of Helena, a municipal corporation, owned and operated a water supply system from which it furnished water for drinking and domestic purposes on a rental basis. A sewer line installed by the city passed above the Eureka water main through which the city furnished water to the plaintiff. As early as July depressions in the street were noticed over the site where the water main and the sewer crossed. On September 30 the city discovered a break in the sewer line within a few feet of the point of crossing. A fluorescein and salt test to determine whether sewage was entering the water main was negative. Samples of water taken between August 6 and August 20, however, were reported by the state board of health as showing the presence of colon bacilli. On August 20 the first case of typhoid fever was discovered, but seven days later the mayor and the city health officer assured the inhabitants of the city, through the medium of a newspaper, that the water supply was safe and that it was unnecessary to boil drinking water. On or about September 15 the plaintiff, a consumer of water from the city's Eureka water supply system, showed symptoms of typhoid fever. Chlorination was begun on September 14 or 16 and continued until September 26 when the Eureka water supply was discontinued. Following this the outbreak of typhoid fever was promptly controlled. The plaintiff sued the city and from a judgment in his favor the city appealed to the Supreme Court of Montana.

That the water supplied by the city contained typhoid fever germs, said the Supreme Court, is fairly inferable from the facts that after the sewer was repaired the water was shown by tests to be pure and that after the water was chlorinated

there was a sharp decrease in the number of typhoid fever cases and shortly thereafter no more cases developed. The evidence supported a finding by the jury that the city had failed to use reasonable care to safeguard the purity of its water supply. The city cannot furnish water to its inhabitants which it knew, or in the exercise of reasonable care should have known, was polluted with sewage escaping from a defective sewer pipe, without assuming liability for damages occasioned thereby.

Judgment in favor of the plaintiff was affirmed.—*Safransky v City of Helena (Mont.)*, 39 P (2d) 644

AMERICAN ASSOCIATION FOR THE STUDY AND CONTROL OF RHEUMATIC DISEASES

Fourth Conference on Rheumatic Diseases

Report of Proceedings at Atlantic City N. J. June 10, 1935

In the last fifteen years there has been a marked increase in the interest taken by physicians in the care of patients with arthritis. Fifteen years ago there were perhaps twenty American "rheumatism specialists." Now there are more than a hundred physicians in this country aside from spa physicians whose major concern is the arthritides. The American Committee for the Control of Rheumatism has had a large share in stimulating this interest by holding demonstrations and conferences at the time of annual sessions of the American Medical Association. Two years ago the increasingly large unorganized audience took matters into its own hands and formed the American Association for the Study and Control of Rheumatic Diseases. Last June at Atlantic City, the Fourth Rheumatism Conference was held on the occasion of the second meeting of the association. The modest room, of a size previously quite ample, was completely filled, many standing even in the adjacent hall. In eight hours nineteen papers and seventy-six discussions were presented.

The conception of chronic arthritis as a general and not a local disease is gaining ground. Therefore Dr. Ernest E. Irons of Chicago president of the association emphasized that studies on arthritis must be diverse and include research not only on the joints but on all body tissues and functions in

order to envision the patient as a whole and to study the soil in which arthritis thrives. Although the majority of arthritic patients must be cared for by general practitioners, it may eventually be necessary for the proper study of arthritis to establish hospitals where research may be highly developed by investigators qualified in its medical, orthopedic, bacterial, chemical and metabolic aspects. A few such clinics already exist at certain medical centers. Dr. Irons felt that they will be more successful if developed as part of a large general clinic. Clinics for the treatment of arthritis alone, established apart from other medical projects, may offer superior custodial advantages for patients needing prolonged hospitalization, but such clinics, Dr. Irons thought, are likely to suffer from lack of stimulation from other departments of a general clinic, and the relation of arthritis to medicine as a whole might be jeopardized.

The division of chronic arthritis into two great common types, atrophic (infectious, proliferative, rheumatoid) and hypertrophic (senescent, degenerative, osteo-) arthritis, is serviceable. There is still disagreement as to whether they represent separate entities. Although the majority believe they are Irons reiterated the suggestion that each may not have one different specific cause but that an articular disease may assume this or that course, with the production of one or another type of arthritis by reason of the kind, age and resistance of affected tissues rather than the nature of the initial insult.

Analyzing forty-nine roentgenologic characteristics, Ferguson Kasabach and Taylor of New York concluded that, although varieties of bone atrophy, lipping and zones of erosion are common to the roentgenograms of different types of arthritis (atrophic, hypertrophic, gouty, gonorrheal, and others), each type has its characteristic picture or combination of roentgenographic alterations, which are best seen in roentgenograms of the hands, feet and knees. Key of St. Louis insisted that the clinical observations are more important in diagnosis than roentgenograms, and that a clinical diagnosis cannot be ventured by the roentgenologist unless he knows the approximate duration of the arthritis and whether the part has been in use. Otherwise, an interpretation of the probable type of atrophy of bone, for example, is impossible. Ferguson agreed that this was true and that in some cases of acute gonorrheal arthritis of short duration the roentgenogram may resemble that of old tuberculous arthritis a differentiation possible only if the duration of the disease is known to the roentgenologist. Most roentgenologists who see any overgrowth of bone in a case of articular disease make a diagnosis of 'hypertrophic arthritis,' and if overgrowth is absent the diagnosis becomes 'atrophic arthritis.' Pemberton of Philadelphia felt that radiologists must exhibit a more informed type of scrutiny and must interest themselves in the variable clinical and pathologic aspects of the disease in order that roentgenograms might be interpreted more correctly.

Atrophic (Infectious, Proliferative, Rheumatoid) Arthritis

Organisms, generally green-producing streptococci but occasionally hemolytic streptococci, were found in the blood of 6 per cent of controls and in that of 21 per cent of patients with atrophic arthritis by McEwen, Bunim and Alexander of New York. Agglutinins and precipitins for hemolytic streptococci were found in the blood of 88 and 80 per cent respectively of thirty-seven patients with atrophic arthritis. Precipitins were also found frequently in other types of arthritis, even gonorrheal. Antistreptolysins and antifibrinolysins were found only occasionally by McEwen, but as Dawson of New York said these tests are indexes of recent acute hemolytic streptococcus infection and one would not expect to find them in cases of chronic atrophic arthritis, although they are sometimes found in early acute cases. Cecil of New York felt that these observations favored the infectious theory of the disease and the streptococci so isolated are not contaminants, although it is not yet known how they get into the blood stream. The bacteriologic terminology of the different workers must not lead to confusion, for many streptococci undergo mutation and what one investigator calls *Streptococcus viridans*

may under varying conditions become slightly or frankly hemolytic. Whether a high or low percentage of positive blood cultures and agglutination tests are obtained depends on the selection of cases of atrophic arthritis, whether they are acutely active or smolderingly chronic. Key has been unable to isolate streptococci from articular tissues but finds staphylococci in about a third of the joints so studied.

In cases of atrophic arthritis the sedimentation rate of erythrocytes is generally rapid and in cases of hypertrophic arthritis it is generally normal or but slightly elevated. The rate of sedimentation is believed to depend largely on the concentration of plasma fibrinogen and globulin and on cell volume. To determine the reasons for altered sedimentation rates in cases of atrophic arthritis, Davis of New York studied the various blood proteins. The total protein content of the blood is normal in both atrophic and hypertrophic arthritis but in atrophic arthritis there is an increase in the plasma fibrinogen, a rise in the globulin fraction, and a fall in the albumin fraction. The greatest increase is in the euglobulin fraction. The albumin globulin ratio is frequently less than 1. As the patient recovers, the ratio tends to return to normal. The estimation of the sedimentation rate is therefore a simple way of roughly detecting any alteration in the globulin or fibrinogen content of the blood, provided a correction is made for cell volume. These changes are not found in cases of hypertrophic arthritis and they suggest again that atrophic and hypertrophic arthritis are quite different diseases. The rise in plasma globulin suggested to Davis that atrophic arthritis is an infectious disease, as rises often occur in such diseases. The fall in albumin suggests a factor of malnutrition or vitamin deficiency, or both. In cases of atrophic arthritis, if the plasma albumin is quite low, considerable edema may appear. Restriction of protein may thus be harmful and a generous intake of protein may lessen edema in such cases.

Discussing the possible significance of these alterations, Haden of Cleveland said that he had found somewhat similar changes in cases of hyperthyroidism, a disease presumably not infectious. These observations complete the cycle of reported or reputed metabolic abnormalities in cases of atrophic arthritis. Physicians have long been warned of alterations in the utilization of carbohydrates, apparently present in many cases of atrophic arthritis. At last year's conference alterations in blood fats were stressed, and now alterations in protein fractions. Since the metabolism of purines, several minerals and vitamins have previously been incriminated, one is now at liberty to suspect abnormalities in the whole metabolic spectrum. In any event these interesting observations illustrate how profound and widespread are the disturbances that constitute the syndrome of this disease.

TREATMENT

The value of a generous protein diet in cases of atrophic arthritis with edema has been mentioned. A diet low in carbohydrate has long been considered by some to be the standard diet for patients with atrophic arthritis. To determine whether excess carbohydrate is harmful for such patients, Bowen and Lockie of Buffalo included about 500 Gm of carbohydrate in the diet of eight patients who were observed for from fifteen to sixty-five weeks. The nutrition of the majority improved steadily and they gained from 24 to 50 pounds (11 to 23 Kg). The arthritis was not materially affected and in general no exacerbations were noted. Insulin given to some did not increase the appetite or augment the effect of the diet. No changes in respiratory metabolism were noted. Some workers in discussion interpreted these remarks as the launching of a new diet for the already overdieted arthritic patient. They merely indicated that a fairly generous supply of carbohydrate was obviously not harmful to the arthritic patient and that Bowen and Lockie felt that restrictions in carbohydrate were of no particular merit either. It was mentioned that in patients whose atrophic arthritis was temporarily inactivated completely by intercurrent jaundice the administration of from 400 to 600 Gm of carbohydrate daily for many weeks did not counteract the analgesic effect of jaundice or bring out symptoms of arthritis.

Bauer of Boston was doubtful that vitamin deficiency plays an important part in the production of atrophic arthritis. No

different results were obtained by a group of his patients who for from three to five years adhered to a special high vitamin diet than were obtained by a group who did not.

Hartung of New York believed that the hematopoietic and leukopoietic functions of the body do not respond properly in the presence of the toxemia or infection causing atrophic arthritis. The infection may be so low in virulence that bone marrow is not stimulated, or there may be a fundamental hormone deficiency somewhat like that in pernicious anemia. Since nucleic acid, one of the disintegration products of leukocytes, is known to stimulate the myelopoietic function of bone marrow, Hartung decided to administer a concentrated extract of leukocytes intragluteally to ten patients daily for long periods. Six patients showed prompt symptomatic and constitutional improvement. There was, however, no change in the appearance of the blood cells or in the sedimentation rate. The effect was not specific and may have resulted from a nonspecific protein reaction, but it was obtained more quickly, was more lasting and was superior to that obtained by him with any other foreign protein.

Snyder of New York and his colleagues were of the opinion that cinchophen, a very useful drug, has been condemned unjustly. Reviewing all reported cases of cinchophen toxicity, they concluded that in only a few was cinchophen unmistakably responsible. After having administered cinchophen to 2,560 patients in ten years, they observed but one case of catarrhal jaundice. Urticaria developed in a few cases but severe jaundice or atrophy of the liver in none.

Physical therapy is perhaps the most helpful form of treatment, but it is used inadequately. Coulter of Chicago was of the opinion that, to supplement the limited sessions of professional physical therapy which patients could afford, the intelligent ones and their relatives should be fully instructed in simple methods of physical therapy that could be applied in the home. Thus the cost of the patient's care could be reduced and the physician could control the patient over the long periods necessary for treatment. By demonstrations and mimeographed instructions Coulter teaches his patients the optimal types and amounts of heat, massage and exercise, the use of cheap but effective electric "bakers" whirlpool baths, and a simple machine for the production of sinusoidal-faradic current, and various appliances for specific, harmless exercises. In Massachusetts alone there are about twenty-two arthritic patients for every physician, and according to Ober of Boston about 70,000 patients receive no treatment whatever. But before home physical therapy can be safely prescribed physicians themselves must learn its principles and methods. A visiting team of physicians, nurses and physical therapists skilled in the management of arthritis should go among local physicians. Ober felt that only under the supervision of the local physician should a visiting physical therapist teach and prescribe home physical therapy. He mentioned that 75 per cent of his arthritic patients have previously sought the services of cultists, who gave them cheap sometimes pain-relieving treatments for which, generally, no substitute had been given by the physician. Unless the better forms of professional and home physical therapy are utilized more fully, patients will continue to flock to the spine and foot twisters.

After summarizing the results from various parts of the country, Ober found that fever therapy, which has proved so helpful in cases of gonorrheal arthritis, does not cure chronic atrophic arthritis. Of a total of 315 patients so far treated in different clinics only 5 per cent became symptom free. Twenty-five per cent were notably relieved. The remainder received little or no benefit. Results are somewhat better in cases of acute atrophic arthritis. Of twenty-one patients so treated 10 per cent seemed completely relieved, 40 per cent notably helped. Stansby of New York and Bauer of Boston agreed that remissions are occasionally induced but that fever therapy should not be used to the exclusion of other measures.

Simpson of Dayton, Ohio, and Shands of Durham N. C., felt that fever therapy given just before or after orthopedic manipulations augmented the benefits of the latter. The recognition of impending deformities is the responsibility of the attending physician who according to Swaim of Boston should early seek the full cooperation of an orthopedic colleague.

Hypertrophic (Senescent, Degenerative, Osteo-) Arthritis

From the roentgenologic point of view, as Haden pointed out, there are several types of "hypertrophic arthritis," including that seen in traumatized joints and in certain stages of gout, gonorrheal, atrophic and other forms of arthritis. "Primary hypertrophic arthritis" represents an entity and results from degeneration of joint cartilage, with proliferation of subchondral bone, incident to physiologic aging and the wear and tear of continued use. Analyzing fifty such cases to determine the accelerating factors of the disease, Haden concluded that infection is a minimal factor and that obesity and an altered metabolic rate (low in 84 per cent of cases) are the common provocatives, the correction or prevention of which may do much to lessen the incidence and disability of hypertrophic arthritis. Bauer and Bennett studied the knee joints of persons from the first to the ninth decade of life. Beyond the second decade the degenerative changes that lead to hypertrophic arthritis were found with increasing frequency, so that by the fifth decade all knee joints were so affected. Some persons inherit better cartilage than others. The poorer the inheritance and the greater the endogenous and exogenous trauma to which the cartilages are subjected, the earlier will hypertrophic arthritis develop. Davis, as noted, found little or no changes in the sedimentation rate or in blood proteins in hypertrophic arthritis, and Dawson found no agglutinins to hemolytic streptococci. In a discussion on fever therapy it was stated that patients with hypertrophic arthritis were not particularly benefited by it.

Gonorrheal Arthritis

The gonorrheal fixation test is of great aid in confirming a clinical diagnosis of gonorrheal arthritis, according to McEwen and his colleagues. It was positive in 98 per cent of forty-three cases. Dawson also felt that the test is of great value, but Key warned that in a case of chronic nongonorrheal arthritis associated incidentally with acute gonorrheal urethritis a positive complement fixation test might lead to error regarding the etiology of the arthritis.

In a summary to the conference on the results to date in various parts of the country of fever therapy in the treatment of gonorrheal arthritis it was noted that 80 per cent of 151 patients with acute gonorrheal arthritis have apparently been cured and that an additional 10 per cent have been markedly relieved. The results in chronic gonorrheal arthritis (of more than six weeks' duration) are less striking but also good. Of thirty-two such patients treated, 35 per cent were cured and 30 per cent markedly relieved. The joints are apparently sterilized rapidly by the bacteriolytic effect of several hours of fever at 106 to 107 F. Bauer and Simpson both reported excellent results and considered fever therapy the treatment of choice and almost specific for gonorrheal arthritis. No untoward reactions were reported except by Snyder, who noted progressive uncontrollable and fatal hyperpyrexia induced by fever therapy in one case of gonorrheal arthritis.

Rheumatic Fever

A review by Nichol of Miami of the available data again indicates that there is much less rheumatic fever in southern than in northern states. During the past five years, for example, the admission rate of patients with rheumatic fever, rheumatic carditis and chorea in a general hospital in Miami was only a tenth of what it was in Boston. Levine of Boston stated that in New Orleans the incidence of mitral stenosis was a twentieth of that in Boston, and he concluded that there is either much less rheumatic fever in the South or that it does not affect the heart as it does in the North.

Of 342 rheumatic children observed by Shapiro of Minneapolis over a period of eight years 52 per cent had only one attack, 48 per cent had recurrences generally within the first four years after the initial attack. This is probably the normal expectancy of recurrences. The majority of "growing pains" of children are not rheumatic. Shapiro distinguished the latter from rheumatic growing pains as follows: The "norrheumatic variety" are usually diffusely and vaguely located in the legs, appear or are worse at night are not associated with fever, and produce no limping or significant stiffness during the day.

The "rheumatic variety" are less diffuse, are more commonly articular, are generally better at night if the patient is warm and worse in the daytime and on walking, particularly during the first hour of the day, and are often associated with a little fever, articular swelling, and heat. Children with growing pains of the latter variety are in danger of rheumatic carditis.

Swift of New York reviewed current ideas on the nature of rheumatic fever. The tissues of patients with this disease apparently are unusually vulnerable to certain injurious agents, especially streptococci or their derivatives. Although it has not been proved that streptococci or a virus are the cause of the disease, the rheumatic patient must be protected, particularly from streptococcal infections, in order to prevent or diminish relapses. McEwen found streptococci, chiefly *Streptococcus viridans*, in the blood of 24 per cent of patients with rheumatic fever and in 6 per cent of controls, agglutinins to hemolytic streptococci were found only occasionally. Precipitin tests were positive in 50 per cent of cases, and antistreptolysin and antifibrinolysin titers were generally, though not always, high.

Rinehart of San Francisco advanced the idea that rheumatic fever may be the result of the combined influence of deficiency in vitamin C and infection. He reported that in guinea pigs on a diet devoid of vitamin C, which were inoculated with a guinea-pig strain of hemolytic streptococci or other organisms, cardiac and articular lesions developed with considerable frequency, notably resembling those of rheumatic fever. Guinea pigs infected with these organisms but on an adequate diet did not show such lesions, and those treated with a deficient diet alone showed only slight lesions. In the discussion of this paper, doubts were expressed as to whether the articular lesions were rheumatic or scorbutic. Swift agreed that lesions of some sort were thus experimentally produced, but he stated that clinical proof was lacking that there was any difference in the metabolism of vitamin C between rheumatic and nonrheumatic patients. Patients with the active and quiescent rheumatic fever were treated with cevitamic acid. Patients with the active form were not benefited and those with the quiescent form later had the usual number of recurrences.

TREATMENT

Kaiser of Rochester, N. Y., urged tonsillectomy for every rheumatic child. According to his large statistics the child who has had his tonsils out is less likely to have rheumatic manifestations and, if he does have them, serious cardiac complications are less likely to develop. Although the incidence of recurrent attacks is not influenced by tonsillectomy, the mortality among 600 rheumatic children was about twice as high as for those who had tonsils at the time of the initial attack, as for those whose tonsils had been removed. Kaiser stated that tonsillectomy, however, does not influence the incidence of chorea or muscular rheumatism. The most definite indication for tonsillectomy in children is a history of repeated attacks of tonsillitis.

Vaccine seemed of little value to Stroud of Philadelphia. As many recurrences occurred among his patients who were treated with vaccine as among a control group.

Chorea

Fever reactions to typhoid vaccine given daily for several days were found by Sutton and Dodge of New York to shorten attacks of chorea an average of thirty-six days, as compared with results when physical therapy, drugs and diets were used. The average duration of the attacks of 150 patients treated by vaccine reactions was 85 days, that of 150 patients treated otherwise 426 days. By means of one or two sessions of fever therapy at 105 to 106 F for five hours, results as good as with vaccine were obtained in sixteen cases. Fever therapy is preferable, as foreign protein shock is avoided, the fever is controllable, and only two sessions instead of several daily reactions are necessary. An associated, active rheumatic carditis does not interfere with such therapy. Indeed, in several cases in which such treatment was employed signs of carditis diminished. It was noted that Sutton and Dodge's results with fever therapy in the treatment of chorea are similar to those reported in twenty-five cases at the Fifth Fever Therapy Conference and in ten cases at the Mayo Clinic.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below

Eosin Methylene Blue Agar for Count of Endamoeba Coli—Gehm and Hueckeleian compared eosin methylene blue agar with and without crystal violet (1 100 000) and found that although the presence of crystal violet cuts down the contaminants, it also cuts the colon numbers to an extent that would prohibit its use as a direct counting medium. Eosin methylene blue agar is prepared according to the standard method except that the use of 2 per cent rather than the usual 15 per cent of agar gives a firmer surface for smearing. Plates are poured to a depth of about 3 mm. One cc of the inoculum is run on the surface of the medium and smeared with the pipet so that the entire surface is covered. The plate is then tilted back and forth several times so that a more even distribution is obtained. The plate is placed in a 37 C incubator and the cover is removed. Drying of the inoculum occurs in about one hour. To obtain perfect distribution it is necessary to tilt the plate, as done at the start when the plate is about half dry. When the surface is thoroughly dry, the plate is closed, inverted and incubated twenty-four hours and characteristic colonies are counted. Contamination from leaving the agar surface exposed in the incubator was practically nil in incubators that were not particularly clean. The dyes present in the medium evidently inhibit bacteria that may be deposited on the agar surface with the dust from the air. Plates containing between thirty and 100 Endamoeba coli colonies give the most consistent counts. As the authors were interested in applying this method to sewage in various stages of treatment and heavily polluted waters, comparative counts were made against the brilliant green bile broth count. The results show a close agreement of the counts by the two methods. In thirteen cases out of nineteen the counts by the eosin methylene blue agar method were higher than those by brilliant green broth bile. They found the method particularly adaptable to sewerage plant control and sewerage research. Application of this method to river waters not heavily polluted appears possible. In this work a comparison should be made with lactose broth with eosin methylene blue confirmation to see whether the inaccurate, cumbersome enrichment count may be omitted entirely.

- Familial Occurrence of Xanthoma Tuberosum**—Lane and Goodman report two cases of generalized xanthomatosis in a father and daughter both with cardiac lesions, one with a history of an acute rheumatic attack and the other with a history of repeated sore throat and tonsillitis. Rheumatic scarring may result in secondary xanthomatous deposits on the endocardium just as trauma results in deposits on the skin. A third case is reported occurring in a child in the same family with an elevated value for serum cholesterol but without cutaneous lesions. This child may have had the underlying fault in metabolism, but the various lipid values may have risen in such proportion that the equilibrium was maintained and no deposits resulted.

Iodine in Therapy of Syphilis—Burke states that *Spirochaeta pallida* is rich in lipids—lecithin and globulin. The essence of the interaction between the parasite and the host is the setting free into the circulation of dead lipoprotein material. The plasma cells are the carriers of a lipoproteolytic ferment. The richer the lipid constitution of the parasite, the greater is the affinity of the ferment for it. The lipoproteolytic ferment has an attraction toward the lipid-rich tissues of the host. In the patient whose system is producing a satisfactory amount of lipoproteolytic ferment, the affinity between the remedial agents and the lipid body tissues becomes reduced, because there has become interposed between the two a barrier consisting of the ferment. There is, thus more of the arspenamine or bismuth available to attack the parasites which have been repelled to the tissues not so well protected. The Wassermann and other serologic tests are simply means of detecting the presence and the amount of lipoproteolytic ferment in the serum. Iodine possesses the property of being able to link itself with or to saturate the lipoids that are present in the blood of a syphilitic person. When these lipoids are saturated, they are no longer able to combine with the natural ferments and so neutralize them. From the beginning of the syphilitic infection there is a tendency for the essential lymphocyte and plasma cell reaction to progress in the direction of fibrosis. It is prudent, then, to neutralize from the earliest moment the power of the lipoids by saturating them with iodine. As a prophylactic measure iodine should be given in every case of acute syphilis concurrently with arspenamine or a bismuth compound, for it has no spirocheticidal effect of its own. Iodine acts not directly but indirectly on abnormal fibrous deposits by reactivating or liberating the normal autolytic ferments of the blood. If these ferments are active there can be no excessive fibrosis, and hence the iodides are inert. They can exert their power only when the fibrosis is excessive and for that reason no amount of iodine therapy can cause the disappearance of ordinary scar tissue, no matter what may be its origin. Such scars are reparative and not of syphilitic origin in spite of the fact that the agent that gave rise to them was *Spirochaeta pallida*. In the stage before a scar is formed however, iodine and the iodides are most assuredly indispensable. No agent other than iodine possesses

the same power of rapidly causing the disappearance of gummas and gummatous infiltration. The mode of action of the spirocheticidal drugs and of iodine differs entirely, although the end results may be similar so far as fibroblastic lesions are concerned. Short of complete scarring, the denser the fibrous tissue the more need there is for the iodides to open the way for the assault by the spirocheticidal drugs. The usual manner in which iodine is administered in the treatment of syphilis is orally in the form of the potassium or the sodium salt. The author's experience has shown that the most satisfactory mode of administering iodine in the treatment of syphilis is in the colloidal form concurrently with arsphenamine or a bismuth compound.

Treatment of Dermatophytosis with Trichophytin—Traub and Tolmach gave 135 patients having dermatophytosis intradermal injections of trichophytin. Apparent cures were obtained in fourteen cases, but some of the patients showed early recurrence. Varying degrees of improvement were noted in fifty-eight cases. Many of these patients returned showing either no further progress or exacerbation of symptoms. In sixty-three cases no change was observed or the patient's condition was made worse by the treatment. In their experience trichophytin apparently had little if any effect on the course of dermatophytosis. In view of the publicity that this treatment has attained among general physicians the authors believe that the comparatively small percentage of cases in which definite benefit was obtained hardly warrants such a tedious and relatively expensive course of treatment in the average case. They used two different preparations of trichophytin and did not note any difference in the results obtained. Of all their patients for whom a diagnosis of dermatophytosis had been made clinically, 21 per cent showed a negative reaction to intradermal injections of trichophytin. The value of injections of trichophytin cannot be accurately determined if effective local treatments are given concomitantly. It is well known that the use of boric acid alone can be of great help in some cases of dermatophytosis. In view of the fact that a patient with dermatophytosis frequently shows periods of remission and relapse, they feel that the reporting of cures and good results in cases of this disease should be more conservative.

Slipping of Capital Epiphysis of Femur—Sutto examined microscopically the tissues removed surgically from three patients with slipping of the capital epiphysis of the femur. They exhibited evidence that the condition is one of a fracture through the upper femoral epiphyseal plate and contiguous trabeculae of bone. No definite evidence of primary degeneration of the epiphyseal plates was seen. Variations in the weight bearing forces at the hip joint may be a predisposing factor in the causation of the fracture. The normal tilting of the capital epiphysis, which is the result of normal developmental and mechanical forces, is the basis for the condition. Slipping of the capital epiphysis of the femur must be sharply differentiated from secondary coxa vara due to fractures, tumors, cysts or pathologic infiltrations, such as is seen in cases of Gaucher's disease. The congenital type of coxa vara may, if uncorrected in childhood, be mistaken for slipping of the capital epiphysis. In the former condition the neck is much more involved than the capital epiphysis, in the latter, changes in the angle of the neck to the femur are secondary to the position of the capital epiphysis. It is especially important to differentiate Perthes' disease from slipping of the capital epiphysis of the femur. Perthes' disease is characterized by aseptic necrosis of the capital epiphysis without any great disturbance to the epiphyseal plate. Changes in the shape of the slipped capital epiphysis are secondary to mechanical factors and not part of the disease.

Streptococcal Peritonitis—In eight cases of streptococcal peritonitis that Felsen and Osofsky studied there was a definite antecedent history of sore throat. The average period that elapsed between the angina and the onset of acute abdominal symptoms was 58 days. The average duration of the disease from the time abdominal symptoms were noted until death was 47 days. The onset was abrupt. In three cases the condition of the throat had cleared up prior to the development of peritonitis. Three adults and five children were affected. In two of the adults the organism was nonhemolytic, but the general features were the same with both the viridans (five cases) and the nonhemolytic type (three cases). Extremely high temperatures were seen in both groups (from 107 to 107.8 F). The initial leukocyte count was high. The Schilling counts indicated active response of the marrow. The pathologic picture in each case was essentially that of streptococcal septicemia with profound toxic effects. The lesions were most evident in the lungs, liver, spleen, intestine, mesenteric nodes and kidneys. The histopathologic pictures in general were congestive or hemorrhagic owing to a toxic effect on the walls of the smaller vessels. Many of the clinical features noted in their studies have been described by other investigators. In most of the reported cases a hemolytic streptococcus was isolated. They believe that their group is exceptional since five cases were of the viridans and three of the nonhemolytic type. The early appearance of diarrhea was absent in almost all their cases. The mortality was 100 per cent. In the experimental work the disease was reproduced in most of their animals by the intravenous injection of eighteen-hour broth cultures. The ease with which they did this, even with some old cultures, suggests the possibility of a selective affinity of their strains for the intestine and peritoneum.

The clinical features of the disease generally known as primary streptococcic peritonitis point to the throat as the primary source of infection in most cases in which a careful history is obtainable. The mechanism of peritoneal involvement may be directly through the blood stream, but the authors are of the opinion that it occurs through the focal hemorrhagic and ulcerative lesions in the intestine. There is ample experimental evidence to support this contention.

Peripheral Neuritis and Abortion Following Dinitrophenol Therapy.—Epstein and Rosenblum present an instance of peripheral neuritis and abortion occurring in an obese woman following the administration of dinitrophenol. On entry to the hospital the blood gave a positive test for alpha-dinitrophenol according to the method of Bolliger. The evidence presented strongly suggests that the peripheral neuritis in this patient was due to dinitrophenol. Numerous instances of patients suffering from pains and paresthesias in the extremities while on dinitrophenol medication have been reported. The neuritis developed in this patient while the drug was being taken and disappeared within three weeks after its administration was discontinued. Compounds chemically closely related to dinitrophenol have caused true peripheral neuritis. The abortion might have been due to the drug passing through the placenta

and causing the death of the fetus, or the mechanism might be analogous to the early premature separation of the placenta sometimes seen in hyperthyroidism. The absence of any discoverable etiologic factor except dinitrophenol makes it probable that the drug was responsible for the abortion. The importance of these two complications makes it advisable that the possibility of dinitrophenol causing peripheral neuritis and miscarriage be brought before the medical profession.

Resistance of Red Blood Cells to Hemolysis in Sodium Chloride Solutions.—Daland and Worthley submit a method for determining the resistance of the red blood cells to hypotonic sodium chloride. The amount of solution and the amount of red cell suspension are kept uniform throughout. The careful reading of the end-points makes it possible to observe slight variations in the resistance of the red cells. Normal maximal resistance occurs in pernicious anemia and lymphatic leukemia. Increased maximal resistance may be found in various sorts of hypochromic anemia, erythroblastic anemia (Cooley's), polycythemia rubra vera and myelogenous leukemia, depending on the degree of anemia present. In idiopathic thrombocytopenic purpura and hemophilia the changes are apparently consistent with the degree of hypochromic anemia. After splenectomy in hemolytic jaundice and occasionally in pernicious anemia during treatment a temporary hypochromic blood picture may be accompanied by increased maximal resistance. Decreased maximal resistance is usually found in hemolytic jaundice and in advanced aplastic anemia. Normal minimal resistance may be found in moderate degrees of hypochromic anemia, including that of purpura, hemophilia, Banti's disease, sometimes in pernicious anemia and in polycythemia vera. Rarely it is normal in hemolytic jaundice. Increased minimal resistance occurs in pernicious anemia in severe relapse and in aplastic anemia. Decreased minimal resistance is usually found in hemolytic jaundice and may be found in hypochromic anemia, erythroblastic anemia, polycythemia vera and myelogenous leukemia. In general, with the exception of hemolytic jaundice and pernicious anemia in remission the standard deviation of the cell diameters increases as the span of resistance increases. This variation in cell diameter is somewhat representative of the heterogeneity of the cell population and may be better correlated with variations in resistance than mean values. In hypochromic anemia, as the standard deviation cell diameters from the mean decrease as a result of therapy there is a progressive decrease in the span of resistance. The increased maximal resistance in hypochromic anemia, Cooley's anemia and polycythemia rubra vera is associated with a lowered mean corpuscular volume and mean corpuscular hemoglobin concentration. The latter may be important in causing flattening of the erythrocytes observed by Haden in this condition. According to the theory of Gänsslen the numerous poikilocytes should be an additional factor making for increased resistance since they present striking deviations from the spherical form associated with a decreased resistance in hemolytic jaundice.

Relationship of Amidopyrine to Agranulocytosis.—To investigate the effect of amidopyrine on the white and differential blood count, Stenn undertook a study of 120 animals—guinea-pigs, rabbits and monkeys—over a period of eight months. Amidopyrine was given orally to one group in doses from a fraction of a grain to 3 drachms (12 Gm.) and blood and differential counts were taken daily. The symptoms were stupor, diarrhea and loss of weight. Many of the animals died of pneumonia and some from amidopyrine poisoning but at no time was agranulocytosis observed. This work was repeated with subcutaneous intraperitoneal and intravenous injections but no change in the blood picture occurred. With another group an attempt was made to sensitize some of the animals treated and these were given a rest period of one month after which the medication was again given still without effect. Incidentally a pregnant guinea-pig was injected with huge doses of the drug for one and a half months, but the newborn guinea-pig and the mother both had normal blood pictures. A group of animals was bled daily until the red blood count fell between 1,500,000 and 2,000,000 and the red cells in the smear showed anisocytosis, poikilocytosis and polychromasia. Despite this preparation the white blood count failed to fall on prolonged administration of amidopyrine. In another group small quantities of benzene in olive oil were injected subcuta-

neously until a severe neutropenia and anemia were produced. In most of the animals the white blood count fell to below 1,500. To half of this group amidopyrine was given orally, and these animals showed a more rapid rise in the white blood count and polymorphonuclear differential picture than the other animals not given the drug. A third group of animals was starved for five days and the drug administered, but without avail. A fourth group of animals was injected subcutaneously with broth cultures of *Bacillus subtilis*, *Streptococcus viridans* and *Salmonella supestrifer*, and one month later, with the infection still persisting, they were given heavy doses of amidopyrine orally during three weeks. The white blood counts were elevated during the period of amidopyrine treatment, and the differential counts showed a predominance of polymorphonuclear leukocytes.

Selenium in Determination of Nonprotein Nitrogen—Reis and Powers used selenium in the determinations of nonprotein nitrogen in blood filtrates, their aim being to develop a method of digestion as rapid and as convenient as the Folin-Wu method but without the troublesome formation of a precipitate of silica due to the action of the phosphoric acid of the digestion mixture on glass. As a result of several preliminary experiments they found that 45 per cent sulphuric acid containing a small amount of selenium could be substituted for the Folin-Wu digestion mixture with but little sacrifice of the length of digestion time and with no formation of silica precipitates. Either selenium or selenous acid may be used. The best results were obtained with a solution of 70 mg of selenium in 200 cc of a 45 per cent solution of sulphuric acid. The digestion is carried out in much the same way as with the Folin-Wu method. In place of the charring seen in the latter method, a rust-colored precipitate of reduced selenium appears. This dissolves as the heating is continued and the digest becomes practically colorless within thirty seconds to three minutes after the appearance of the fumes of sulphur dioxide. Five minutes of heating from the first appearance of the acid fumes is sufficient for the complete digestion of most samples of urine and for all blood filtrates, unless these filtrates, through improper preparation, contain traces of protein. In the selenium sulphuric acid method this trace of protein goes into solution but is quite difficult to digest. Usually an additional five minutes of heating completes the digestion and, if a slight brown color still persists after ten minutes of digestion, it may be disregarded as it apparently does not affect the accuracy of the determination. Analyses were done on urine and on known solutions of urea and uric acid. For the urine a value of 107 Gm of nitrogen per liter was obtained as compared with 10.64 Gm with the Folin-Wu method. The urea solution gave a value of 3.35 mg of nitrogen per hundred cubic centimeters as compared with the calculated value of 3.5 mg. A lithium carbonate solution of uric acid on one analysis gave a value of 3.29 mg of nitrogen per hundred cubic centimeters and on a second analysis, 3.33 mg as compared with a calculated value of 3.33 mg. By the use of gum ghatti the authors succeeded in nesslerizing solutions that were milky with precipitated tungstic acid, although in some cases the solution would have to stand for several minutes before all the tungstic acid was dissolved by the alkali of Nessler's solution.

Oral Manifestations of Bismuth.—McCarthy and Dexter state that the high incidence (80 per cent) of bismuth pigmentation in the mouth, in a series of 511 cases of syphilis under treatment in a hospital clinic, indicates that local oral hygiene and tartar deposits seem to represent the important factor. The contact buccal mucosal pigmentation is shown to be definitely due to irritation from the opposing gingival irritant, which is essentially tartar. Severe cases of gingival pigmentation and inflammatory reaction are relatively few, and over a period of about ten years since the preparation of insoluble bismuth salicylate in oil has been in use the number of cases of necrosis and gangrene has been extremely rare. Therefore this drug may be considered a safe therapeutic agent in the treatment of syphilis, as the presence of pigmentation and mild gingivitis seems to have no deleterious effect on the general health of the patient. A series of urinary examinations in a selected group of severe cases of pigmentation with gingivitis was negative for evidence of nephritis. Chronic nephritis was present in the two cases reported and this condition is definitely a factor in the production of local gangrenous processes, although susceptibility to the drug undoubtedly may play an important part. Examination of the blood of a small group of patients showed no dyscrasia related to bismuth therapy. In contrast to the hospital cases studied in this series, a small control group of office patients under bismuth salicylate therapy showed a low incidence of pigmentation, about 5 per cent. Poor oral hygiene is the important factor that predisposes to pigmentation in the oral cavity. Removal of tartar deposits with improved dental hygiene hastens the disappearance of pigmentation and tends to prevent further deposits.

Treatment of Psoriasis with Organic Sulphur Compound.—Thurmon describes a solution in which the total sulphur averages 0.185 per cent by weight and is distributed possibly as 30 per cent allyl sulphide, 25 per cent polysulphide, 35 per cent allyl mercaptan, 7 per cent polymer (insoluble material) and possibly 3 per cent thio acid. Each cubic centimeter of the final solution contains about 2 mg of sulphur. The solution may be administered with safety intravenously, intramuscularly, intracutaneously, subcutaneously, orally, by inhalation in the form of a spray and by injection as an ointment. Blood counts and examinations of the urine repeatedly performed on patients during and following the sulphur intravenously, have failed to reveal any abnormal change, except that occasionally patients will show a slight increase in the blood

cell count and hemoglobin, the latter increasing from five to fifteen points, the white cells to a count ranging between 9000 and 10,000 and the red cells at times increasing as much as 1.2 million per cubic millimeter when the count is below normal. In the fifty-eight patients treated, other complications were pregnancy, diabetes mellitus, alimentary glycosuria, biliary cirrhosis, infectious jaundice, postarsphenamine hepatitis, essential hypertension, cardiorenal disease, aortic dilatation and insufficiency, generalized arteriosclerosis, and orthostatic albuminuria. The drug was administered to these and to two additional patients during the febrile period of erythema multiforme with out untoward reaction. Repeated examination of the optic fundi has failed to reveal any toxic manifestation. In all cases syphilis has been ruled out as an etiologic factor. It is advisable to start each patient on treatment three times a week until ten or twelve injections of organic sulphur have been administered. For an adult, 10 cc is the initial dose, the subsequent dosage ranging from 15 to 25 cc, depending on the response of the individual lesions. From the beginning a bland ointment is used that keeps the psoriatic scales soft and flexible, prevents and alleviates dryness, pruritus and the irritation occasionally encountered in the thickened, roughened and fissured plaques. The first change noted after the initial two or three injections is that the psoriatic areas are transformed into a vivid pink to cherry red. The process of involution continues at a pace varying with the individual response of each patient until the areas are devoid of scales but are present as smooth soft pink thin, flexible papular elevations. Finally the papules become erythematous macular areas, easily blanched with pressure and eventually disappear when involution is completed. No pigmentation or roughness of the skin remains to mark the site of previous involvement. Intravenous organic sulphur is not a cure for psoriasis. With proper administration of the drug it is possible to control psoriasis and to effect a complete involution of the eruption. Remissions have been attained that have lasted six months. Other patients in whom complete involution of psoriasis has been accomplished have had recurrences in less than six months, but with additional treatment at the beginning of such a recurrence it is possible to render it completely under control.

*Intranasal or Gastro-Intestinal Portal of Entry in Poliomyelitis J A. Toomey Cleveland—p 200
Hemorrhagic Necrosis and Regression of Sarcoma 180 G Schwartzman New York—p 201

Portal of Entry in Poliomyelitis—Toomey feels that poliomyelitis in the monkey results when monkey cord virus and the toxic material in the animal's intestine combine and the combination material destroys motor cells. In the human being the causative agent usually enters the digestive system "ready made," i.e., it is already combined and capable of producing cell destruction immediately. All the vagaries of the disease both in the *Macacus rhesus* monkey and in the human being even the reason why the lumbar area usually seems to be involved first, are easily understood in the light of this theory. Much experimental and clinical work has been done that points to a relationship between the gastro-intestinal tract, the sympathetic nervous system and the production of the experimental disease. But ignoring this evidence, when virus is given either intracerebrally or intranasally, the experimental animal usually gets quadriplegia and dies. Poliomyelitis is thus produced but even though this is poliomyelitis it is not the kind that is seen in man. The objective should be to produce the disease as it appears clinically. If poliomyelitis can be produced in the experimental animal in the same way as it is seen in the human being it is plausible to suppose that the route taken to produce it in the monkey might be the same as that taken by the virus in the human being. The fact that intranasal inoculation is unsuccessful if the connection between the gray-fibered olfactory nerve and the central nervous system is severed is interesting. However transection of the olfactory nerve would be of importance only if such section made it impossible to produce the disease by the gastro-intestinal tract. The author states that, if his theory as to the production of paralysis in the monkey is right, it is obvious that passive immune serum of great value cannot be obtained by injecting monkeys with the virus alone. A high-titered antiserum was rapidly produced by injecting a sheep with these combined factors—virus and enteric toxin—and recently the author has produced paralysis in a horse by injecting these combined elements.

Persistence of Tetanus Antitoxin in Man—During the last two years, Sneath and Kerslake have determined the antitoxin content in the blood serum of a group of adults at various intervals after subcutaneous injections of tetanus toxoid. Serum was obtained from thirteen persons about two years after the last dose of the primary series of injections of tetanus toxoid. Of twelve persons in whom comparison was possible, the residual antitoxin showed no evidence of having fallen below that shown from twelve to fifteen months after the last dose. Three of the group retained at least 0.1 unit of tetanus antitoxin per cubic centimeter. In view of the limitation to accurate interpretation of the tests, the apparent increases in antitoxin titer shown by three of the group during the second year cannot be accepted without reserve. If subclinical infection by *Clostridium tetani* were a possible explanation of such a delayed antitoxin increase, acting in this instance as a secondary stimulus, it is probable that a higher residual titer would be found than was shown. It is therefore considered that the apparent increase in antitoxin titer over this period is probably not significant. A fourth dose of toxoid was given to these twelve persons and serum was obtained at intervals of a week and a month thereafter. Within a week an increase in antitoxin titer occurred in the order of from ten to five hundred times more than the residual level shown two years after the primary series. After a month, five showed a further increase in antitoxin titer, four showed no appreciable change, two showed a definite fall and one serum was not tested. Eleven persons developed tetanus antitoxin in amounts of between 0.1 and 10 units per cubic centimeter. One subject, whose titer did not rise above 0.025 unit, has shown a poor antitoxin response throughout. Nevertheless, the increase is similar in trend to that of the other members of the group. A fourth subcutaneous dose of 1 cc. of tetanus toxoid given to fourteen persons about a year after a primary series of three doses has been shown to occasion a rapid increase of antitoxin within a week, thirteen of the group attaining or exceeding an antitoxin titer of from 0.1 to 0.25 unit per cubic centimeter, which level was maintained after a month. A year later one subject had retained approximately the same antitoxin titer as was found a month after the fourth dose, whereas in the others the titer had definitely fallen. Nine persons retained antitoxin in amounts varying from 0.1 to 0.75 unit per cubic centimeter, these residual levels in general being substantially in excess of those found a year after the initial doses.

 Treatment of Acute Suppurative Otitis Media by Syringing with Alcohol V. Schmidt—p. 594

Relation of Blood Vessels of Nasal Wall to Sinuses

—Burnham investigated the course and relations of the blood vessels of the lateral nasal wall and accessory sinuses. Comparatively large bony canals are present in the central part of the middle and posterior half of the inferior turbinate bones. They contain terminal branches of the turbinate arteries, veins (jacket plexus) which form an essential part of the 'venous pathways,' and nerves. The veins and nerves are enclosed in the periosteum that surrounds the artery. Owing to the delicate structure of the canals, they may be almost entirely destroyed in a macerated specimen and this may account for the vagueness

of the descriptions. Three definite canals are present in the posterior half of the inferior turbinate. The uppermost contains vessels for the antrum, and its connection with the latter through the 'uncinate aperture' is described. This aperture is a constant naso-antral bony opening, inferior to the uncinate process, through which the antrum obtains a large part of its blood supply. In the central third of the middle turbinate, a single canal terminates anteriorly in three smaller divisions. The term 'venous pathways' is used to indicate the large channels of veins that carry the blood over the lateral nasal wall to the sphenopalatine foramen. They are the inferior, middle and superior turbinate venous pathways. Each pathway is made up of erectile vessels, which pass into either periosteal or 'intra-osseous' veins, and each of these joins the jacket plexus of veins within the bony canals of the turbinate. They then leave the canals, passing into periosteal veins again before reaching the sphenopalatine foramen. The intra-osseous veins are mainly present in minute bony canals in the anterior half of the middle and inferior turbinates. The erectile tissue empties directly into these veins; very few arterioles are associated with them. The erectile tissue also passes into the periosteal vessels that accompany the larger arteries. These periosteal veins enter the large bony canals in the posterior half of the turbinate and are continuous with the jacket plexus which the latter contains. A few of the periosteal veins also accompany the arteries that pass over the lateral nasal wall to the sphenopalatine foramen. They are, however, of distinctly minor importance compared to the large bony canal channels. The superficial veins of the lateral nasal wall present such sharp turns and twists in their courses that they may be described as convoluted. This is particularly true of the erectile tissue areas. The periosteal veins, on the other hand, both those found within the large turbinate canals and those on the surface, have a more wavy course with much fewer and less abrupt turns. The veins of the sinuses are of the periosteal type and, from the plexus about the ostium, take a comparatively straight course into the sinus. This ostial plexus is but a few millimeters in width, except in the case of the antrum, in which it covers a large part of the medial wall. The vessels pass into the sinus and either end in capillaries or are conjoined to collateral branches. In the sinus, no definite superficial layer of veins has been found and a distinct contrast is evident between the straight coursed veins of the sinus and the convoluted ones of the lateral nasal wall. The erectile (cavernous) tissue vessels present pouches or pockets in their walls, continuous with the lumen of the vessel but enlarging it considerably.

- *Relative Value of Cholecystography and Gallbladder Excretion Test in Diagnosis of Cholecystitis M Chiray I Pavel and A Lomon —p 1265

Pleural Pressure Baillet —p 1267

Cholecystography and Gallbladder Excretion Test in Diagnosis of Cholecystitis—Chiray and his collaborators studied the relations of the Meltzer-Lyon test and cholecystography to disease of the gallbladder and biliary tract. It is obvious that a negative cholecystogram can be related to a pathologic state of three organs without counting the sphincter of Oddi, whereas the negative Meltzer-Lyon test indicates the gallbladder alone as the cause. Thus cholecystography is principally valuable when positive, while the Meltzer-Lyon test has theoretically the same value for positive and negative tests. In the biologic study of gallbladder disease by those means three possibilities arise. When both duodenal drainage and the cholecystogram give a normal response it is almost certain that the gallbladder is not involved. When both tests are abnormal, it is almost equally certain that there is a diseased gallbladder present. When the two tests are divergent, the diagnosis involves real difficulties. The most common difference is when cholecystography gives a negative or questionable image and the Meltzer-Lyon test shows a 'B bile' of variable character. In these cases the latter indicates the true diagnosis. In the inverse case, when cholecystography gives a positive result and duodenal drainage is negative, pericholecystitis is most often the cause. In conclusion the authors state that the two tests are not always superimposable and that one cannot be substituted for the other but they are complementary and the employment of both does much to increase the diagnostic accuracy to an extent previously unknown.

Influence of Adrenal Cortex Extract on Bactericidal Power of Blood—Calderera administered two subcutaneous injections of 0.2 cc. of adrenal cortex extract twenty-four hours apart to a number of rabbits. The bactericidal power of the blood was determined in each animal before treatment and two, eight and twenty-four hours after the second injection. Blood was taken from each animal and added to an equal amount of physiologic solution of sodium chloride citrated at 15 per cent. One cubic centimeter of the citrated blood was placed in each of two tubes. One drop of a 1:40,000 suspension of *Staphylococcus aureus* was added to the blood in one tube and a similar proportion of colon bacillus to the other. The tubes were placed in an incubator at 37 C for three hours after which the blood plates were prepared. At the same time a control plate was prepared with a mixture of 1 cc of physiologic solution of sodium chloride citrated at 15 per cent with one drop of bacterial suspension. The number of colonies developing on the control plate and on the blood plate were compared. The author found that the bactericidal power of the blood is constantly increased by the use of adrenal cortex extract. Plates of blood obtained two hours after injection of extract showed a diminution of bactericidal power (greater development of colonies) while those obtained after eight hours showed a marked increase. Those obtained after twenty-four hours showed a tendency of the bactericidal power to return to normal. This tendency varies according to the micro-organism used. The bacterial index of *Staphylococcus aureus* for example was higher after twenty-four hours than in the beginning, while the bacterial index of colon bacillus after twenty-four hours was on a par with or lower than the initial values.

Spontaneous Pneumothorax Due to Rupture of Subpleural Bubbles—Castex and Mazzei report twelve cases of benign spontaneous pneumothorax due to rupture of subpleural bubbles. They state that the disease develops in persons (especially men) ranging in age between 22 and 30. All the authors' patients were men. There were no symptoms of tuberculosis in evolution. The disease is afebrile and lasts about four weeks ending in recovery without leaving signs of any pathologic process that can be detected in the roentgen examination of the lung. There is slight or no pleural effusion. The diagnosis is confirmed if the bubbles are visible in the roentgenogram as happened in three of the authors' cases. Active or latent tuberculosis does not play a part in the etiopathogenesis of the disease. The bubbles, the size and number of which are variable, may be located in different parts of the lung, such as the apex, borders, aspects and fissures. As a rule they originate in pleural scars. Inflammatory processes and congenital malformation of the lung have been noted. The treatment is one of expectation and consists chiefly in rest and symptomatic remedies. If there are complications, such as circulatory shock and acute anoxemia, the employment of anaesthetics and of oxygen is advised. Only in one of the authors' cases was part of the pleural air removed.

- *Serologic Differential Diagnosis Between *Brucella Abortus* and *Brucella Melitensis* Infection in Human Subjects. H Habs and Lena Sievert —p 1398

Angioid Streaks—Reichling observed three patients with angioid streaks in the retina. Two of these patients had a careful dermatologic examination, which however, gave negative results. Although the presence of pseudo-*anthoma elasticum* could not be proved in his cases, the author is inclined to agree with other observers who consider the disorder a systemic disease of the elastic substance.

Differential Diagnosis of *Brucella Abortus* and *Brucella Melitensis*—Habs and Sievert point out that a differentiation of the various types of *Brucella* is desirable from the epidemiologic point of view. In cases in which the causal organism can be cultured, the differentiation is rather simple. However in practice, the specific diagnosis is usually based on the outcome of the immunity reactions particularly the agglutination. Formerly the agglutination test did not permit a differentiation. But since the studies carried out by Wilson and his collaborators have provided a better understanding of the antigen structure of the various *brucella* types, the authors considered new tests advisable. Wilson had demonstrated that only the smooth strains should be used, because the rough strains produce disturbances. He had found also that the difference between *abortus* and *melitensis* groups is not that in addition to a common group antigen they also each have a specific antigen but rather that both groups contain two identical antigens in differing quantities. Thus there is really only a quantitative difference between the two types. The authors state that although their observations differed slightly from those of Wilson, they were able to corroborate the fact that it is possible to differentiate the *melitensis* and *abortus* types by quantitatively graded absorption experiments. Former experiments had for an object the classification of the *brucella* group into different types by means of rabbit immune serum. In the experiments described here, the opposite method was employed, that is by means of known strains it was attempted to determine

Relation of Blood Vessels of Nasal Wall to Sinuses—Burnham investigated the course and relations of the blood vessels of the lateral nasal wall and accessory sinuses. Comparatively large bony canals are present in the central part of the middle and posterior half of the inferior turbinate bones. They contain terminal branches of the turbinate arteries, veins (jacket plexus) which form an essential part of the "venous pathways," and nerves. The veins and nerves are enclosed in the periosteum that surrounds the artery. Owing to the delicate structure of the canals, they may be almost entirely destroyed in a macerated specimen and this may account for the vagueness

of the descriptions. Three definite canals are present in the posterior half of the inferior turbinate. The uppermost contains vessels for the antrum, and its connection with the latter through the "uncinate aperture" is described. This aperture is a constant naso-antral bony opening, inferior to the uncinate process, through which the antrum obtains a large part of its blood supply. In the central third of the middle turbinate, a single canal terminates anteriorly in three smaller divisions. The term "venous pathways" is used to indicate the large channels of veins that carry the blood over the lateral nasal wall to the sphenopalatine foramen. They are the inferior, middle and superior turbinate venous pathways. Each pathway is made up of erectile vessels, which pass into either periosteal or "intra-osseous" veins and each of these joins the jacket plexus of veins within the bony canals of the turbinate. They then leave the canals, passing into periosteal veins again before reaching the sphenopalatine foramen. The intra-osseous veins are mainly present in minute bony canals in the anterior half of the middle and inferior turbinates. The erectile tissue empties directly into these veins; very few arterioles are associated with them. The erectile tissue also passes into the periosteal vessels that accompany the larger arteries. These periosteal veins enter the large bony canals in the posterior half of the turbinate and are continuous with the jacket plexus which the latter contains. A few of the periosteal veins also accompany the arteries that pass over the lateral nasal wall to the sphenopalatine foramen. They are, however, of distinctly minor importance compared to the large bony canal channels. The superficial veins of the lateral nasal wall present such sharp turns and twists in their courses that they may be described as convoluted. This is particularly true of the erectile tissue areas. The periosteal veins, on the other hand, both those found within the large turbinate canals and those on the surface, have a more wavy course with much fewer and less abrupt turns. The veins of the sinuses are of the periosteal type and, from the plexus about the ostium, take a comparatively straight course into the sinus. This ostial plexus is but a few millimeters in width, except in the case of the antrum, in which it covers a large part of the medial wall. The vessels pass into the sinus and either end in capillaries or are conjoined to collateral branches. In the sinus, no definite superficial layer of veins has been found and a distinct contrast is evident between the straight coursed veins of the sinus and the convoluted ones of the lateral nasal wall. The erectile (cavernous) tissue vessels present pouches or pockets in their walls, continuous with the lumen of the vessel but enlarging it considerably.

- *Relative Value of Cholecystography and Gallbladder Excretion Test in Diagnosis of Cholecystitis M Chiray I Pavel and A Lomon —p 1265
Pleural Pressure Baillet—p 1267

Cholecystography and Gallbladder Excretion Test in Diagnosis of Cholecystitis—Chiray and his collaborators studied the relations of the Meltzer-Lyon test and cholecystography to disease of the gallbladder and biliary tract. It is obvious that a negative cholecystogram can be related to a pathologic state of three organs without counting the sphincter of Oddi, whereas the negative Meltzer-Lyon test indicates the gallbladder alone as the cause. Thus cholecystography is principally valuable when positive, while the Meltzer-Lyon test has theoretically the same value for positive and negative tests. In the biologic study of gallbladder disease by those means, three possibilities arise. When both duodenal drainage and the cholecystogram give a normal response, it is almost certain that the gallbladder is not involved. When both tests are abnormal, it is almost equally certain that there is a diseased gallbladder present. When the two tests are divergent, the diagnosis involves real difficulties. The most common difference is when cholecystography gives a negative or questionable image and the Meltzer-Lyon test shows a 'B bile' of variable character. In these cases the latter indicates the true diagnosis. In the inverse case when cholecystography gives a positive result and duodenal drainage is negative, pericholecystitis is most often the cause. In conclusion the authors state that the two tests are not always superimposable and that one cannot be substituted for the other, but they are complementary and the employment of both does much to increase the diagnostic accuracy to an extent previously unknown.

Influence of Adrenal Cortex Extract on Bactericidal Power of Blood—Calderera administered two subcutaneous injections of 0.2 cc. of adrenal cortex extract twenty-four hours apart to a number of rabbits. The bactericidal power of the blood was determined in each animal before treatment and two, eight and twenty-four hours after the second injection. Blood was taken from each animal and added to an equal amount of physiologic solution of sodium chloride citrated at 15 per cent. One cubic centimeter of the citrated blood was placed in each of two tubes. One drop of a 1:40,000 suspension of *Staphylococcus aureus* was added to the blood in one tube and a similar proportion of colon bacillus to the other. The tubes were placed in an incubator at 37 C for three hours after which the blood plates were prepared. At the same time a control plate was prepared with a mixture of 1 cc of physiologic solution of sodium chloride citrated at 15 per cent with one drop of bacterial suspension. The number of colonies developing on the control plate and on the blood plate were compared. The author found that the bactericidal power of the blood is constantly increased by the use of adrenal cortex extract. Plates of blood obtained two hours after injection of extract showed a diminution of bactericidal power (greater development of colonies) while those obtained after eight hours showed a marked increase. Those obtained after twenty-four hours showed a tendency of the bactericidal power to return to normal. This tendency varies according to the microorganism used. The bacterial index of *Staphylococcus aureus* for example was higher after twenty-four hours than in the beginning while the bacterial index of colon bacillus after twenty-four hours was on a par with or lower than the initial values.

Spontaneous Pneumothorax Due to Rupture of Subpleural Bubbles—Castex and Mazzei report twelve cases of benign spontaneous pneumothorax due to rupture of subpleural bubbles. They state that the disease develops in persons (especially men) ranging in age between 22 and 30. All the authors' patients were men. There were no symptoms of tuberculosis in evolution. The disease is afebrile and lasts about four weeks ending in recovery without leaving signs of any pathologic process that can be detected in the roentgen examination of the lung. There is slight or no pleural effusion. The diagnosis is confirmed if the bubbles are visible in the roentgenogram, as happened in three of the authors' cases. Active or latent tuberculosis does not play a part in the etiopathogenesis of the disease. The bubbles, the size and number of which are variable, may be located in different parts of the lung, such as the apex, borders, aspects and fissures. As a rule they originate in pleural scars. Inflammatory processes and congenital malformation of the lung have been noted. The treatment is one of expectation and consists chiefly in rest and symptomatic remedies. If there are complications, such as circulatory shock and acute anoxemia, the employment of anaesthetics and of oxygen is advised. Only in one of the authors' cases was part of the pleural air removed.

*Serologic Differential Diagnosis Between *Brucella Abortus* and *Brucella Melitensis* Infection in Human Subjects H Habs and Lena Sievert—p 1398

Angioid Streaks—Reichling observed three patients with angioid streaks in the retina. Two of these patients had a careful dermatologic examination, which however, gave negative results. Although the presence of pseudoxanthoma elasticum could not be proved in his cases, the author is inclined to agree with other observers who consider the disorder a systemic disease of the elastic substance.

Differential Diagnosis of *Brucella Abortus* and *Brucella Melitensis*—Habs and Sievert point out that a differentiation of the various types of *Brucella* is desirable from the epidemiologic point of view. In cases in which the causal organism can be cultured, the differentiation is rather simple. However, in practice, the specific diagnosis is usually based on the outcome of the immunity reactions, particularly the agglutination. Formerly, the agglutination test did not permit a differentiation. But, since the studies carried out by Wilson and his collaborators have provided a better understanding of the antigen structure of the various *brucella* types the authors considered new tests advisable. Wilson had demonstrated that only the smooth strains should be used, because the rough strains produce disturbances. He had found also that the difference between *abortus* and *melitensis* groups is not that in addition to a common group antigen they also each have a specific antigen but rather that both groups contain two identical antigens in differing quantities. Thus there is really only a quantitative difference between the two types. The authors state that although their observations differed slightly from those of Wilson they were able to corroborate the fact that it is possible to differentiate the *melitensis* and *abortus* types by quantitatively graded absorption experiments. Former experiments had for an object the classification of the *brucella* group into different types by means of rabbit immune serum. In the experiments described here, the opposite method was employed, that is by means of known strains it was attempted to determine

by absorption experiments the agglutinin content of the serum of patients and thus find whether the patients had a *Brucella abortus* or a *Brucella melitensis* infection. At first the authors followed the technic suggested by Wilson, but later they modified it in various ways. They give several tabular reports, indicating the observations on various serums. On the first, a *melitensis* serum, absorption experiments were made with a *melitensis* strain on the one hand and with an *abortus* strain on the other. The absorbed serum was further combined with another *abortus* strain, with a *suis* strain and with two additional *melitensis* strains. The table indicates that, following the absorption with the *melitensis* strain, none of the *abortus* strains became agglutinated. Following absorption with the *abortus* strain, however, only the agglutinins for the *abortus* strains and the *suis* strains were withdrawn, whereas the *melitensis* strains were still agglutinated up to one fourth of the original serum titer. Thus it is proved that the serum was from a patient with *Brucella melitensis*. The authors describe tests on several other serums.

Function of Thyroid and Heart—Parade discusses the circulatory mechanism in case of dysfunction of the thyroid. He emphasizes that the thyroid is an important link in an interconnected system in which the sympathetic centers of the diencephalon, the hypophysis, the sympathetic nervous system, the adrenal cortex, and other incretory organs play a part. In discussing the effects produced by the hypofunction of the thyroid on the heart and the circulation, he points out that during starvation there develops a bradycardia as manifestation of a hypofunction of the thyroid and that hibernation in animals is accompanied by an involution of the thyroid and a great reduction in the frequency of the pulse. In human myxedema one observes bradycardia and a slowing down of the circulation and of the metabolic processes. If, however, under the influence of thyroid medication the myxedema symptoms disappear, the heart action likewise improves. The close relation between thyroid and heart is proved further by the fact that the administration of thyroid extract is followed by acceleration of the pulse and other cardiac symptoms if too large doses are given. The author discusses the cardiac function in hyperthyroidism. He shows that the increased rate of the basal metabolism in exophthalmic goiter is accompanied by accelerated circulation. He points out that absolute arrhythmia with auricular fibrillation is relatively frequent in older persons with exophthalmic goiter. He emphasizes that, if old persons have a cardiac insufficiency of obscure etiology, particularly if the insufficiency does not respond to digitalis and is accompanied by auricular fibrillation, a thyrogenic origin should be considered and the proper therapeutic measures should be taken to counteract the thyrotoxicosis.

Nervous Disturbances in Pernicious Anemia—Straube summarizes his observations on the nervous symptoms of patients with pernicious anemia, compares his observations on certain points with those of other investigators and pays especial attention to the therapeutic aspects. In discussing the etiology, he expresses the opinion that funicular myelitis as well as other organic nervous disturbances are not the result of the anemia, for they have been known to precede the anemia, but that the anemic as well as the spinal symptoms may have

a common cause. After discussing the histologic aspects and the incidence of the spinal symptoms, he gives his attention to the question whether funicular myelitis has become more frequent since the era of liver therapy. He thinks that the patients survive longer, which allows more time for the development of funicular myelitis. In reviewing the literature on the therapeutic amenability of the spinal symptoms, the author observed great discrepancies not only in the selection of the therapeutic method but also in the estimation of the results. However, he found that all those who employed liver therapy in a large number of cases agree that funicular myelitis is not favorably influenced by the liver therapy. At the author's clinic several hundred cases were observed. The liver therapy had the desired effect on the blood status and the general symptoms, but, in spite of the fact that excessive doses of liver were given in the hope that a therapeutic effect might be exerted on the spinal symptoms, the results were negative. To be sure, in some instances the paresthesias and the disturbances of sensitivity improved, but these improvements were, as a rule, not lasting. The author concludes that the spinal symptoms which accompany pernicious anemia cannot be cured and cannot even be prevented. However, he does not think that treatment should be entirely omitted but suggests that the combined administration of strychnine, arsenic, phosphorus and liver may eventually be effective. Moreover, he thinks that general tonicizing measures, such as walking exercises, massage and hydrotherapy, might be helpful.

The Agglutination Test and *Brucella Abortus* Infection—Hauptmann points out that the occurrence of positive *Brucella abortus* agglutination reactions in healthy persons and in patients with other disorders, which he observed in the course of tests on 2,315 serums, limits the diagnostic value of the agglutination test. The existence of a *Brucella abortus* infection is the more likely, the higher the agglutination titer is above the 1:100 ratio. However, there is no definite boundary line that applies to all cases. The author stresses that the positive outcome of the *Brucella abortus* agglutination test should not induce the diagnostician to give up the thought that typhoid or paratyphoid might be present. Complementary examinations will be necessary in order to reach a definite diagnosis.

Sulphur in Experimental Carbon Monoxide Poisoning—Voit and Schmidt direct attention to studies conducted by Vita and Salmoiraghi. In animal experiments on the action of colloidal sulphur in carbon monoxide poisoning, these investigators were able to show that guinea-pigs treated with sulphur survived carbon monoxide poisoning and recovered in a relatively short time while the control animals died. When the animals were exposed to fatal doses those which had received prophylactic injections of sulphur survived three times as long as those which had not. In spectroscopic studies on the detoxication mechanism in experimental carbon monoxide poisoning it had been determined that at the time the signs of poisoning disappear there appears a blood spectrum that greatly resembles the spectrum of carbon oxy-sulphide in the blood. From this observation it was deduced that carbon oxy-sulphide is formed in the blood during carbon monoxide poisoning and that this is a detoxication process. It was thought that the injection of sulphur might accelerate the formation of carbon oxy-sulphide. The authors decided to investigate whether the prophylactic treatment with sulphur would prevent the development of erythrocytosis, leukocytosis and hyperglycemia, which frequently develop in the course of carbon monoxide poisoning. They studied the action of sulphur on acute as well as on chronic cases. They found that the injection of sulphur prevents the development of hyperglycemia and of erythrocytosis. The observation of Vita and Salmoiraghi that the animals

treated with sulphur have a greater resistance to carbon monoxide poisoning could be corroborated in the majority of animals, but not in all

Congo Red in Treatment of Intestinal Hemorrhage—Szirmai considers severe intestinal hemorrhage one of the gravest complications of typhoid, and, in order to control it in several cases of typhoid that were under his treatment, he followed Pely's suggestion and employed intravenous injections of congo red. He points out that congo red belongs to the electronegative, neutral, high molecular dyestuffs. In experiments it was proved to be nontoxic, and it was found to increase the blood platelets, the monocytes and the coagulability of the blood. The author employed congo red in ten typhoid patients with severe intestinal hemorrhages. In four cases a single intravenous injection of 10 cc of a 1 per cent solution stopped the hemorrhage, while in the other cases two or three injections were necessary. The repeated injections are given at intervals of twelve or twenty-four hours. Aside from mild attacks of chills that developed in two patients, there were no harmful results from the congo red.

*Influence of Diuretics on Alkali Reserves of Blood G. Gottsegen —p. 1116

Foreign Body Tumors of Colon—Manizade describes a case of foreign body tumor of the colon presenting the aspects of a malignant neoplasm. Not until after a careful anatomic examination was it possible to exclude the existence of a malignant neoplasm, and this examination revealed also the real cause of the chronic inflammatory process, namely, a small foreign body (chicken bone). Although it is generally assumed that swallowed foreign bodies are discharged from the intestine by the natural route as soon as they have passed the duodenal flexure and the ileocecal valve, a review of the literature discloses that occasionally inflammatory tumors arise on the basis of a foreign body lodged in the lower portion of the intestine. It appears that the sigmoid is most subject to such processes, since this section of the intestine favors the lodging of foreign bodies because of its flexures and the retarded passage of the intestinal contents. However, another observer has suggested that the size of the lumen plays a part in the lodging of and perforation by a foreign body. The author, on the other hand, cites a case in which retardation of the passage and flexure of the intestinal tube were responsible for perforation by a foreign body. The peculiar postoperative course in the first patient, that is, the recurrent inflammatory tumor, induced the author to search for the causes of this behavior. He points out that Weltmann's coagulation reaction is helpful not only in differentiating chronic inflammatory tumors and neoplasms but also in detecting a change in the protein coagulation which in turn would explain the development of such hyperplastic tumors. In the reported case the Weltmann reaction disclosed an extremely wide coagulation band. This outcome of the test favors definitely a chronic productive process and militates against a neoplasm but also indicates why the foreign body gave rise to such extensive inflammatory proliferation. The author points out that persons with dental prostheses particularly if the prostheses cover the entire palate, readily swallow comparatively large bodies without noticing them.

Influence of Diuretics on Alkali Reserve of Blood—Gottsegen thinks that it cannot be doubted that changes in the acid base equilibrium are of great importance for the water economy of the organism. He cites the opinions of several other investigators and then reports studies carried out by himself. He found that mercury diuretics (salyrgan and others), ephylline and sodium dehydrocholate increase the alkali reserve of the blood. The mercury compounds have the strongest action in this respect, the bile acid the weakest. The combination of mercury salts with sodium dehydrocholate changes nothing in regard to the development or the extent

of the alkalosis. Ammonium chloride inhibits the alkalosis only if its administration is continued following the injection of the diuretic. If it is given only before, the alkali reserve increases in the same manner as if only the mercury compound had been given. The diuretic action of ammonium chloride cannot be ascribed entirely to the acidosis that develops, but it may be assumed that various changes in the internal milieu play a part.

*Results of Serum Treatment in Peritonitis O. Kapel —p. 2053
*Thrombophlebitis Migrans (Saltans) and Its Etiology J. Jákó —p. 2056
Interesting and Rare Complications of Adhesion Ileus A. Adler —p. 2059
Cancer Caused by Arsenic Case S. Miyaji —p. 2063

Serum Treatment of Peritonitis—Kapel says that he has employed a combination of a serum obtained by the immunization of horses with the toxins of selected colon strains with a so-called peritonitis serum prepared in the same manner by means of *Bacillus perfringens*. The ampules of colon serum contained 25 cc and the ampules of perfringens serum contained 20 cc. In severe cases the author administers the first dose intravenously together with an infusion of a sodium chloride solution while the patient is still under the anesthetic. The same dose is also given intramuscularly. On the following five days the patient is given daily one ampule of each of the two serums intramuscularly. In the case of children, the injections are given for only three days. In cases in which the general condition is not noticeably impaired, the intravenous injection is omitted and only the intramuscular injections are given. The author employed serotherapy in all cases of diffuse, free perforation peritonitis, in the majority of cases of localized perforation peritonitis in cases in which there was an accumulation of pus around the vermiform process and finally in cases in which large portions of the appendix were gangrenous so that the bacteria could penetrate. In investigating the results of this serotherapy, the author finds that it produced no changes in the total mortality rate. Nevertheless, he gained the impression that the serum exerted a beneficial effect in patients who recovered for the signs of general intoxication were less severe than is otherwise the case. The intestinal function was reestablished in a shorter time, and the recovery was more rapid. The serotherapy had the disadvantage that in some instances it resulted in arthralgias, exanthems, edemas and fever, but these disturbances were only temporary. He concludes that further experimental studies will be necessary in order to determine whether these serums really contain antibodies. He is inclined to believe that these serums are only antibacterial, not antitoxic.

Thrombophlebitis Migrans (Saltans)—According to Jákó, thrombophlebitis migrans differs from ordinary thrombophlebitis in the manner in which it appears and in its clinical symptoms. It usually appears in the superficial, peripheral veins. Another characteristic is that it appears in widely distant regions. The author points out that the term "migrans" is really not quite suitable for the relapsing thrombophlebitis generally does not spread progressively although this too is possible, but advances by leaps leaving healthy sections in the same vein and suddenly appearing in a distant vein. For this reason he thinks that the term thrombophlebitis "saltans" would be more fitting. As a rule, thrombophlebitis migrans (saltans) appears without preliminary symptoms but occasionally spasm-like pains precede it. He reports two cases, in describing the histologic aspects he points out that all layers of the venous wall show signs of inflammation. Many investigators consider the etiology unknown. He rejects Buerger's opinion according to which thrombophlebitis migrans is supposedly an accompanying symptom of thrombo-angitis obliterans. Other investigators consider syphilis or tuberculosis a causal factor, but they do not furnish definite proof for this. The author thinks that the clinical aspects indicate that an infection of low virulence is the cause. However, in addition to an infectious origin, a characteristic reaction of the veins plays a part. It is chiefly the latter factor that differentiates the process from the ordinary type of thrombophlebitis. He is of the opinion that thrombophlebitis migrans (saltans) is an allergic problem. He thinks that a hypersensi-

tivity is involved and that a disturbance in the sympathetic nervous system plays a part in this hypersensitivity. The infectious cause should be given especial attention. In the reported cases a latent infectious focus in the teeth was the eliciting cause. The search for and the elimination of the latent infectious focus is one of the most important factors in the treatment.

- *Computation of Basal Metabolic Rate from Pulse Frequency and Pulse Pressure by Means of Read's Formula Annemarie Oettinger—p 2124
- Case of Congenital Sarcoma E. Kubany—p 2126

Disinfection by Solution of Formaldehyde—After pointing out that the use of tincture of iodine in the disinfection of the operative field has certain disadvantages, Borchers states that for about nine years he has used a 5 or 10 per cent alcoholic solution of formaldehyde. He proved the suitability of the formaldehyde preparation in practice and by experiments. He describes comparative tests, and in summarizing his observations he states that (1) the immediate influence of the alcoholic solution of formaldehyde on the bacterial content of the skin is better than that of tincture of iodine, (2) its lasting action on the bacteria of the skin is better than that of tincture of iodine, (3) injuries of the skin (dermatitis, necrosis) are almost never observed, if the application of the formaldehyde has been suitable, (4) exudation from the puncture channel occurs only in a small number of cases, and (5) solution of formaldehyde is much less expensive than tincture of iodine.

Computation of Basal Metabolic Rate—Oettinger calls attention to the fact that Read's formula makes the determination of the basal metabolic rate comparatively simple in that it does not require the use of a complicated apparatus but computes the metabolic rate according to the following formula: Basal metabolic rate = 0.75 (pulse rate + 0.74 pulse pressure) — 72. In order to determine the reliability of the formula, the author made comparative tests on fifty-nine persons, that is, she determined the basal metabolic rate by means of an apparatus and also computed the rate according to Read's formula. In the majority of cases she found only slight discrepancies. She also was able to corroborate Read's statement that his formula does not give reliable results in persons less than 15 and more than 55 years of age, in those with a blood pressure in excess of 160 mm of mercury, in patients with severe disturbances in the cardiovascular-renal system and in severe cardiac lesions. She concludes that, even with these limitations, the formula is valuable for use in the clinic and for the general practitioner.

Influence of Iron and Phosphorus on Pregnant Organism—Schub made studies on ninety-six pregnant white rats. One half of this number of animals served as controls. The latter were given food that was deficient in iron and phosphorus. The other animals received in addition to the same food organic iron and organic phosphorus. Every third day the animals were carefully weighed. Already on the fifth day the experimental animals showed an increase over the controls. The increase in weight during the entire period of observation was 38 Gm in the rats that received no addition of iron or phosphorus and 63 Gm in the animals that received the addition. The offspring of the control animals weighed 44 Gm and that of the experimental animals 518 Gm. After delivery and the cessation of the iron and phosphorus therapy, the experimental animals lost weight less rapidly than did the controls.

Acta Medica Scandinavica, Stockholm

Pulmonary Bilharziasis Simulating Tuberculosis—Mainzer reports five cases of a chronic infiltrative disorder of the lung which simulated tuberculosis but which was accompanied by an enlargement of the spleen and an excessive eosinophilia and responded to treatment with antimony. The eosinophilia, the treatment, the simultaneous presence of a urinary and intestinal bilharziasis in one case (and a similar report in the literature) and the clinical and experimental aspects of a pulmonary infection in the course of the development of different forms of schistosomiasis favor the assumption that the disorder was a pulmonary schistosomiasis. The author differentiates the described cases of bilharziasis into three groups. The first group, represented by one case, can be designated as bronchial asthma produced by Bilharzia. The second and third groups are pulmonary bilharziasis in the strict sense of the term. The second group includes the acute cases of pulmonary bilharziasis. In this form the foci may completely disappear after the treatment. The third group includes the chronic cases of pulmonary bilharziasis in which a pulmonary cirrhosis remains after the treatment. The author thinks that two reports in the literature under the headings of "familial eosinophilia" and "persistent eosinophilia with enlargement of the spleen" are probably cases of this disease. He emphasizes that pulmonary bilharziasis must be differentiated from the well known pulmonary symptoms that accompany bilharziasis of other organs.

- *Medical Treatment of Congenital Pyloric Stenosis Elisabeth Srenggaard—p 833
- Secondary Pelagra Review of Forty Cases A. Hofman Bang—p 845
- *Sporadic Goiter on Genotypical Basis S. Hanum and J. E. Holst—p 855

Treatment of Congenital Pyloric Stenosis—Srenggaard's material consists of seventy-one patients, from 1911 to 1922, treated with stomach lavage and feeding by duodenal sound, forty-seven from 1922 to 1927 treated with atropine and sixty-one since 1927 treated with atropine methylnitrate. The average hospitalization was, respectively, 108, 96 and 77 days, the mortality 71, 64 and 16 per cent and the average increase in weight per week 62, 91 and 122 Gm. The author emphasizes that treatment with salt solution is important until dehydration is past, when treatment with atropine or atropine methylnitrate is begun, and that the medication is given one-half hour before meals. The grave prognosis for patients with a tendency to hemorrhage is stressed.

Sporadic Goiter on Genotypical Basis—Hanum and Holst report ten cases of goiter in one family, in two generations, one in a man and nine in women or girls. They assert that these cases are definitely distinguished from exophthalmic goiter, although half of the patients have presented symptoms resembling those of exophthalmic goiter. While most of the reported cases of sporadic goiter on a genotypical basis have been nodose, only one of their instances is nodose, in one case information is lacking and in the remaining eight (a father and seven daughters) the goiter is diffuse. Thus difference, they suggest, may be partially explained by the different ages represented, the goiter noted in childhood, as in the seven sisters, most often being diffuse, but other factors are believed also to be present.

THE ETIOLOGY OF HEART DISEASE

WITH SPECIAL REFERENCE TO THE PRESENT STATUS
OF THE PREVENTION OF HEART DISEASE

HOWARD B SPRAGUE, MD

AND

PAUL D WHITE, MD

BOSTON

In the history of our knowledge of circulatory disease the nineteenth century contributed chiefly through its descriptions of structural change in the heart and blood vessels. The present century may become known as the one in which emphasis on causation led to the etiologic classification of heart disease and to the first steps in its prevention. This has proved already to have been a great advance and proceeds most decisively from the work of Cabot¹ in Boston. He attributed the four common types of heart disease to rheumatism, syphilis, hypertension and arteriosclerosis, and these remain the causes of nine tenths of the organic heart disease of the United States. In the remaining one tenth are found such diverse types of heart affliction as congenital, thyroid, acute and subacute bacterial, diphtheritic and toxic heart disease, and the damage to the heart produced by pulmonic hypertension, anemia, trauma, systemic disease and neoplasms. While it is true that heart disease is now thought of in terms of etiology as one of the elements of the triad of diagnosis—etiologic, structural and functional—one must not be satisfied to confuse knowledge with nomenclature, since it must be admitted that in the four major types of heart disease the pathogenesis is obscure in more than 90 per cent. The causes of rheumatism, hypertension and arteriosclerosis are unproved and in this ignorance of the causes lies to date much of the failure of preventive medicine in heart disease.

In the 10 per cent of heart disease with assorted etiology the possibility of prevention depends on the underlying conditions, many of which are remediable, but, except in goitrous districts with an abnormal incidence of thyroid heart disease, not one of these minor groups presents a public health problem of any great importance.

On the other hand, the four major groups constitute a preponderant problem since they are responsible for two and a quarter times as many deaths as their nearest rival, cancer. It appears not too optimistic, however, to believe that three of them—rheumatic, syphilitic and hypertensive—may eventually become amenable to pre-

ventive measures and that even the fourth—arteriosclerotic—may be so controlled that it will cause serious damage only in the aged.

RHEUMATIC HEART DISEASE

Rheumatic infection is a disease the cause of which has been "discovered" by many investigators, but unhappily each time it is a different cause and no one of them has as yet satisfied the criteria for final proof. The disease has not been reproduced unequivocally in animals and disputes have arisen as to the pathognomonic changes in tissue that can be accepted as evidence of the disease. The Aschoff body, necrosis of collagen, perivascular infiltration with round cells, and giant cell formation are the fundamental reactions of human tissues, but only in a limited degree have they been reproduced in animals. More often the response has been that of sepsis or of some nonspecific reaction. Similarly, immunologic investigation has been hampered. The organism most commonly blamed has been *Streptococcus haemolyticus*, and its role in the etiology is at present a hotly disputed point. It has been thought by some to be the cause of the disease, by others the sensitizer to the infection, and by others to play no part but that of the innocent bystander. From the studies to date, there appear certain definite points:

- 1 Rheumatic fever in the United States is predominant in the northeastern part and is a disease of temperate climates. The more carefully it is searched for, however, in regions thought to be relatively free from it, the more frequently it appears to be found, though disguised in less classic form.

- 2 It has a seasonal variability, being more active in the late winter and early spring in this country.

- 3 It is a disease of the lower middle class and is aggravated by crowding and urban conditions. Paul has found it eight times as frequently in children attending public schools in poverty-stricken areas in New Haven as in children attending private schools, which confirms figures from our clinic.

- 4 It tends to be more common in certain families.

- 5 It has an optimal age period for first attacks at from five to twelve years.

- 6 Whatever the underlying virus may be, the disease is capable of reactivation by many nonspecific agents or events, the chief of which is respiratory infection. Accidents, injuries, emotional episodes, surgical operations, nonspecific protein shock and high temperature therapy have been shown by Bland and Jones at the House of the Good Samaritan in Boston to be able to precipitate a recurrence of signs of active infection in rheumatic children.

From this mixture of etiologic factors one can extract a composite ideal recommendation for the pre-

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1935.
¹ Cabot R. C. The Four Common Types of Heart Disease. J. A. M. A. 63: 1461 (Oct. 24) 1914.

vention of the disease. It would seem as if children, especially of well-to-do parents, living in the rural tropics and free from respiratory disease with hemolytic streptococci, would be in the most desirable situation so far as avoidance of rheumatic infection is concerned, they should not migrate to temperate climates in the colder months of the year, since they can develop very severe rheumatism, such as happened to Puerto Ricans studied by Coburn in New York.

It is clear that such a combination of factors as appears in this ideal composite cannot be effected even though it would reduce the prevalence of rheumatic fever, nor, indeed, would it be desirable for many other reasons. From the standpoint of preventive medicine there are two aims for which to strive. The first concerns the actual destruction of the disease by removing the soil in which it flourishes, this is based on the hope that a gradual improvement in the average standard of living may abolish the urban crowding, malnutrition, faulty housing and possibility for direct transmission of disease, which seem the abettors of the rheumatic infection. This is perhaps utopian and remains for the distant future to evolve. As regards the individual case, efforts can be made for the betterment of living conditions which our first aim implies as well as for the recommendations about residence in warm and equable climates.

The second avenue of preventive approach is less concerned with racial betterment but is more immediately applicable. It has to do with the attempt to prevent reactivation of rheumatic fever already acquired by the child but lying quiescent and perhaps associated with only minor cardiac damage. Here it is a matter chiefly of the prevention of respiratory infection. Matters of diet or rest, isolation from family or school contacts with colds and sore throats, and instruction of parents, nurses and teachers are all necessary, as is the appreciation by all who deal with such children that rheumatic infection is of long duration and that the appearance of any one of the many signs of its activity is a requirement for bed care for the child. This second aim, then, is the prevention of involvement of the heart, since this is the crippling damage, although it is now known that the rheumatic disease also attacks all other organs of the body through its effects on mesodermal structures, as shown by the perivascular response.

So far, the use of vaccines, preventive or curative serums, change in immune reactions by nonspecific measures, high or selective vitamin feeding, and attempts to reproduce tropical conditions in institutions in temperate zones have failed to prevent recrudescence of the disease. One variable not controlled, to our knowledge, has been the humidity of the air in hospitals for rheumatic children where temperature regulation and ultraviolet radiation have been used to reproduce tropical weather. Keeping a group of children in such an atmosphere with adequate humidity throughout the winter might be helpful and would more nearly approximate the conditions that we have sought in sending children to Florida from the House of the Good Samaritan.

SYPHILITIC HEART DISEASE

The incidence of syphilitic heart disease is not high in any large group of the population of the United States except the Negro, and even in this race hyper-

tension is more common. In New England the incidence is about 5 per cent and in Texas 19.5 per cent in a combined group of white persons and Negroes, with a percentage of 32 in Negroes alone.² The etiology of syphilitic aortitis became firmly established almost thirty years ago, and with the introduction of modern treatment for the primary infection the possibility of eradication of its effects on the cardiovascular system became apparent. Of the four chief etiologic types of organic heart disease, this is the one seemingly destined the soonest to disappear through the early diagnosis and treatment of its underlying cause. Already there is some evidence of a decrease in aortic syphilis in New England, in the ten years from 1900 to 1909, 51,875 patients were admitted to the Massachusetts General Hospital and the diagnosis of aneurysm of the aorta was made in 113 cases—an incidence of practically 0.2 per cent. In a similar ten year period that ended in 1934, 75,184 patients were admitted and only sixty one aneurysms of the aorta were found, or an incidence of only 0.08 per cent, and this in spite of the improved roentgenologic facilities for diagnosis in the latter period.

HYPERTENSIVE HEART DISEASE

High blood pressure is a tremendously important cause of strain on the heart and leads to cardiac failure by producing fatigue, dilatation, and hypertrophy of the left ventricle. In New England it is a primary or secondary factor in 30 per cent of all organic heart disease. It can be separated from coincident arterio-sclerosis only with difficulty in certain cases, but the present evidence is in favor of the view that when they are combined the arterial hypertension precedes the degeneration of the vessels. The cause of high blood pressure is not known, but innumerable theories have led to the addition to, or subtraction from, the environment of patients with hypertension of such a collection of foods, drugs, joys and sorrows, virtues and vices as would comprise most of the human experience. In many instances the patient has been bettered, in many others he has been made worse, and in both instances his blood pressure has usually remained the same.

It is popular at the moment to blame our modes of living for the increase in hypertension in the belief that emotional hyperactivity results in arteriolar spasm, decrease in peripheral vascular bed, increase in systemic pressure, degenerative changes in arterioles and arteries and an overwhelming burden on the heart. Apparently good evidence has been found which shows that the prevalence of hypertension in different races is in direct ratio to the strains of civilized life rather than dependent on any of the dietary factors that have been such popular culprits. For example, the African Negro is said to be less hypertensive in a state of nature than when exposed to white civilization. It still seems difficult to explain the prevalence of high blood pressure in the American Negro on the basis of emotional tension when a relative freedom from worry has been adduced by some to explain a rather strikingly low incidence of angina pectoris in this group.

There are probably many causes for hypertension—some remediable, did we but know them, and some beyond our power to change in the event that we, as

² Stone, C. T., and Vanzant, Frances R. Heart Disease as Seen in a Southern Clinic, J. A. M. A. 89: 1473 (Oct. 29) 1927.

a nation, choose to continue to live at a constantly accelerating speed

It has been said that the younger members of hypertensive families should be spared the tensions of life, which are thought to lead later to high blood pressure. How that can be done is not clear. All existence is strongly competitive at present and for men to become the objects of public or private charity in no way leads to emotional relaxation, although it may appear to permit physical rest. A compromise, with the avoidance of some strains, is, however, always possible and may make the difference between health and illness.

The newer studies on endocrine factors, carotid sinus reflexes, and pressor substances may lead to preventive measures in the future, but if the mechanism of hypertension is to remain a function of the emotions there seems little immediate hope of its abolition.

ARTERIOSCLEROTIC HEART DISEASE, MUCH BETTER DESIGNATED CORONARY HEART DISEASE

Here a word or two about definitions is of fundamental importance at the start. The unsatisfactory term "arteriosclerotic heart disease" is at last being rapidly supplanted by the expression "coronary heart disease," which might be more accurately given under the cumbersome designation "atherosclerotic coronary heart disease." Arteriosclerosis generally distributed throughout the body or localized even in high degree in organs other than the heart does not cause heart disease, except as severe renal involvement may influence the heart secondarily through much hypertension or the toxic effect of uremia. Coronary arterial disease of any importance is in the very great majority of cases due to an atherosclerotic process and only rarely to infection, narrowing or occlusion of the mouths of the coronary arteries by syphilitic aortitis should not be considered coronary arterial disease any more than the blocking of the vessels by emboli as in bacterial endocarditis, the hypothetical but plausible coronary spasm, if it occurs, may be the result of irritation of the vessel walls by some disease process as well as of nervous vascular irritability. The term atherosclerosis is better than that of arteriosclerosis so far as the coronary arteries are concerned, as many of the most serious lesions, especially in youth, are the result of softening or atheroma, with ensuing reaction, which may occlude the vessels, rather than of sclerotic changes with calcification, which may be only the terminal stage in the aged. Finally, the term angina pectoris is not to be used interchangeably with that of coronary atherosclerosis, it is, to be sure, a symptom which in the great majority of cases does spell much coronary vascular disease, but it is in large part dependent on nervous irritability and sometimes not due to any obvious disease of the coronary arteries themselves, as in syphilitic aortitis when the coronary mouths are narrowed and in extensive aortic valve disease when the blood flow is not normal and an element of vascular spasm is probably superadded. Thus angina pectoris may exist without coronary atherosclerosis, and, much more frequently, coronary atherosclerosis, even of very high degree, may occur without angina pectoris.

Coronary disease occurs as an important factor in the production of heart disease in about 25 per cent of the heart cases in this country.

Coronary disease, as defined, shows itself clinically most commonly by the occurrence of either angina pec-

toris or coronary thrombosis or both, occasionally by certain electrocardiographic changes, namely, auriculo-ventricular or intraventricular block and inversion of the T waves with or without abnormal position of the ST intervals not otherwise explained, and infrequently by congestive failure of the heart without previous warning.

There is one other type of so-called atherosclerotic heart disease that is occasionally encountered and which has been discussed off and on in the past, but not with a very clear estimate of its importance. This is atherosclerosis involving the endocardium and valves, particularly the aortic valve. There is no doubt about the existence of this condition. It probably has much the same basis as atherosclerosis of the arteries, but it practically never assumes any clinical importance. The amount of change is slight. The usual manifestations are a little atheroma or sclerosis on the valve cusps, and especially fibrosis and calcification at the base of the aortic cusps on the aortic side of the valve. Infrequently the aortic valve ring, and very rarely the mitral valve ring, may become calcified and the process may extend a little way up on to the cusps themselves, producing a slight amount of stenosis. This condition involving the aortic valve has been called Monckeberg's sclerosis. The important degrees of valvular stenosis are, however, always on an infectious background even though calcification may be superimposed, that is significant calcareous valve disease is never, so far as we know, the result of a simple atherosclerosis.

The cause or causes of coronary atherosclerosis are not known. They have been the subject of extensive discussion for well over a hundred years now and the International Association of Geographic Pathologists, which met last summer in Utrecht to study arteriosclerosis, was unable to throw any new light of vital importance on the time worn subject. Infection, wear and tear, malnutrition due to lesions of the vasa vasorum, hereditary weakness, and metabolic disorders have been the most popular culprits. At present it is rather the vogue to believe that serious atherosclerotic changes are produced in arteries or portions of arteries that are under the greatest mechanical strain (wear and tear) in individuals who have inherited arteries that are fragile in this particular and who for some unknown reason have been depositing an excessive amount of fat in their artery walls for years, sometimes since early youth. Diabetes and obesity, especially the former, favor the earlier appearance of coronary atherosclerosis.

Coronary thrombosis is still another problem. It is, to be sure, implanted as a rule on coronary artery walls that are badly damaged and in lumens that are much narrowed, but not always. In some cases, at least, a thrombotic tendency appears to exist.

From what we have said it is evident that we cannot do much as yet to prevent coronary atherosclerosis. The advice, which, from our own studies of healthy centenarians and of young persons with coronary disease and from the study of others, we might in our present ignorance bestow, would be "to select good ancestral coronary arteries, to avoid diabetes and excessive obesity or, if they are present, to treat them, and to establish healthy habits of life—in work, leisure, exercise, rest, diet, digestion, and the avoidance of certain poisons like lead, which increase the tendency to arteriosclerosis." Country life and hard physical work,

the avoidance of excessive worries and nervous strains, and the temperate use of tobacco appear to be of some importance in promoting longevity. Finally, why should the male sex be so preponderantly affected? Every one of twenty-five patients of ours with clinical evidence of serious coronary atherosclerosis 40 years of age or under was male and nearly 90 per cent of those under the age of 50 were male, here apparently lies a vital clue.

270 Commonwealth Avenue

AN ANALYSIS OF THE APPARENT INCREASE IN THE HEART DISEASES

ALFRED E. COHN, M.D.
NEW YORK

It seems scarcely necessary to repeat the commonplace that the death rate from cardiac and circulatory diseases is mounting while that from the infectious diseases is falling (chart 1). But it is necessary to insist

Chart 1—Mortality rates per hundred thousand of various diseases in first ten registration states and the District of Columbia 1868-1930. The diseases are grouped as follows: A (infectious diseases). Typhoid, measles, scarlet fever, whooping cough, diphtheria, influenza, mumps, dysentery, acute poliomyelitis, meningococcus meningitis, malaria, and cholera nostras. B (Tuberculosis, pneumonia, and bronchopneumonia). C (circulatory diseases exclusive of acute cardiac diseases). Apoplexy, angina pectoris, other diseases of the heart (including endocarditis), diseases of the arteries, and other diseases of the circulatory system. D (acute cardiac diseases). Pericarditis, acute endocarditis, and myocarditis. The states included are Connecticut, Indiana, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Rhode Island, Vermont, and the District of Columbia.

on this fact in order to raise these questions. First, how do the individuals who died formerly of infectious diseases come to an end? and, second, is it really true

that the increase in deaths from circulatory diseases takes place because of the fall in deaths from infectious ones? It is necessary to show that the fall in the former is actually enough to account for the rise in the latter. A simple calculation shows that this is not true. The decades that are especially involved are those after age 40, for it is in these that the rises in circulatory diseases have taken place. The increases in circulatory diseases are indeed greater than the decreases in the infectious ones. There is, in short, a net increase in the circulatory diseases after age 60. How this takes place can be demonstrated in a set of curves. It should be understood that the figures given describe the condition in the U. S. registration area of 1900. They may be representative of the country as a whole, but, seeing how closely diseases of all sorts are dependent on the environment, the climate in the West and South may actually require a different description of the course of cardiac diseases for these states.

Next, changes have taken place in the diagnoses commonly employed in reporting deaths from circulatory diseases (chart 2). It is clear that beginning with age 40 there has been a rise in the death rate from chronic cardiac diseases, decade by decade, from 1900 to 1930. The same statement can be made about diseases of the arteries until the year 1920. Since then, if diseases from the coronary arteries are excluded, the rate has either fallen or remained constant. In chronic nephritis it is only beginning at age 70 that the rate rose to a high point in 1920, and it has fallen since in every decade. In the diagnosis cerebral hemorrhage and softening there has been a fall in each decade after 1920 and, as against 1900, no rise until age 70. Senility, a diagnosis commonly employed formerly, is made with conspicuously less frequency now. If these five sets of curves are viewed as a whole, it appears that it is only in chronic cardiac diseases that a more or less consistent rise has taken place since 1900 after age 40. In short, these banks of curves show fairly conspicuous tendencies. If all of them are added together, as is done in the last column, the curves appear flatter and exhibit rises of a more or less important nature only after age 60. From this chart alone the conclusion may be drawn that, although there has been a rise in all these diseases taken together since 1900, the rise is not conspicuous.

It has already been stated that there have been savings in every decade in the infectious diseases. It has also been stated that there are increases in circulatory ones in every decade after age 50. Finally, it should be repeated that the increases are somewhat more than the savings, especially between ages 70 and 89. This relation can be shown by studying the facts arranged in a somewhat different way. In each decade it is clear that the rate of all the infectious diseases has fallen (chart 3, curve 2). It is also clear that, beginning with age 50, the curves in each decade showing the combined death rates from circulatory diseases have risen (chart 3, curve 1). If curves 1 and 2 are added it appears that only after age 80 has the fall in curve 2 (infectious diseases) been insufficient to bring about a fall in the combined curves 1 and 2. Here, in short, the savings from infectious diseases just about balance the increases in the circulatory ones so that since 1920 the curves in these decades are flat. One must reckon then with the fact that if, since 1900, there has been on the whole a rise in the death rate from circulatory

diseases, this rise is slight and is due to the fall in infectious diseases. It is a matter of great importance to notice that the fall in infectious diseases has taken place in the very decades in which rises from circulatory diseases occur. The notion which has been prevalent that the increases in circulatory diseases, small as they are relatively, are due to the decrease in the rate of infectious diseases in the early ages of life is therefore incorrect. The savings from infectious diseases which occasion the rises in the circulatory ones take place in the same decade. The reason for the small discrepancy according to which there is a rise in the circulatory diseases at all is not explained in this analysis. Considering the nature of vital statistics, it is not surprising that an exact balance has not been found. The opportunity for error is, of course, very great. It should be pointed out that the result which has been attained in this study should have been anticipated, for, although the number of deaths in circulatory diseases, and indeed from other diseases, may be expected to have risen as a result of doubling of the population in every decade after age 40, between 1900 and 1930 there is no reason why there should have been a change in rate. This should have remained the same except for special alterations in balance, such as are exhibited in the interplay

2 Changes in the diagnoses which have been employed account in part for the interpretation which has been placed on the course of events

Chart 2—Death rates per hundred thousand of population for United States registration area of 1900 for certain diseases

3 The slight rise in the total death rate from circulatory diseases is due apparently to savings from deaths resulting from infectious diseases in the very decades in which the slight rise in the circulatory diseases has occurred¹

Sixty-Six Street and York Avenue

¹ A more detailed account of these studies has been given by Cohn A. E. and Lingg Claire. *Am Heart J* 9: 283 (Feb) 1934

Chart 3—Death rates per hundred thousand of population for United States registration area of 1900 for certain diseases and combinations of these diseases by age groups in 1900 1910 1920 and 1930. Curve A describes the course of the death rates in chronic cardiac diseases. Curve B adds to curve A the death rates in diseases of the arteries. Curve C adds to curve B the death rates in chronic nephritis. Curve D adds to curve C the death rates in cerebral hemorrhage and softening. Curve E adds to curve D the death rates in senility and represents therefore the death rates of this entire circulatory group. Curve F adds to curve E the death rates from tuberculosis. Curve G adds to curve F the death rates from pneumonia. Curve H adds to curve G the death rates from all the other causes of death and describes therefore the total death rate.

between circulatory and infectious diseases. The following inferences may be drawn from this study

1 There has been a rise, but a slight one only, in the death rate from circulatory diseases

effects are to be expected if the cold showers are kept up during menstruation. If a shower is available, there would seem to be no reason why it should not be enjoyed—Novak, Emil. *The Woman Asks the Doctor*, Baltimore, Williams and Wilkins Company, 1935

Bathing During Menstruation.—Should bathing be omitted during menstruation? On this point there has been a considerable change of opinion and practice in recent years. Our grandmothers were certainly as a rule taught that the daily bath must be abjured during menstruation while now many "modern" girls take a daily shower, or perhaps go in swimming, without regard to menstruation. It would be foolish to lay down hard and fast rules in this respect. It can be said, however, that for the girl who has accustomed herself to a cold bath or a cold shower every morning no harmful

THE HEART IN HYPERTENSION

GEORGE FAHR, M.D.
MINNEAPOLIS

The appalling death rate associated with essential hypertension¹ is just beginning to dawn on the medical public. Bell and Clawson² found that 12.6 per cent of all patients over 40 years of age and 14.8 per cent of all patients over 50 years of age coming to autopsy had a history of high blood pressure or showed anatomic evidences of having had hypertension. These figures were partly based on increased heart weight in cases showing no valve defect, adherent pericardium, chronic nephritis or hyperthyroidism. There is some slight error in the assumption that idiopathic left ventricular hypertrophy is always due to increased blood pressure, but this slight error is well balanced by the fact that in some cases of severe hypertension known to have existed for years previous to autopsy the hearts are of normal weight. On the other hand, Bell and Clawson have considered only female hearts over 450 Gm and male hearts over 500 Gm as indicating the presence of hypertension during life. Using the coefficient of variation of 17.7 per cent calculated for normal heart weight by Greenwood³ and assuming that the normal mean female heart weight is 300 Gm and the male is 350 Gm, I have calculated that there is not one chance in twenty that a female heart weighing 400 Gm or a male heart weighing 450 Gm is normal. It can also be calculated that, if Bell and Clawson had used the foregoing heart weights as the upper limits of normal, they would have found that their material showed about 20 per cent of hypertension for patients for the ages above 50 years.

Making use of the official mortality statistics for the registration area of the United States for 1924, I⁴ have calculated that there were approximately 140,000 deaths, or 23 per cent of all deaths, during this year in persons aged 50 years or older in consequence of essential hypertension. This is nearly twice as many as the number of cancer deaths for the same age group. Although there is some error connected with all these figures, they do show that the incidence of hypertension in the general population over 50 years of age is very high indeed and that the death rate in consequence of high blood pressure greatly overshadows the death rate due to any other factor. Since at least 55 per cent of all patients with high blood pressure die of heart failure,⁵ it can be readily seen that knowledge of this most frequent form of heart disease is of paramount importance to the general practitioner.

PATHOLOGIC ANATOMY

In any study of the heart in essential hypertension it is well to begin with the pathologic anatomy of this

organ. With a few exceptions all hearts in which hypertension has been present for some time show a considerable increase in weight. The majority will weigh over 400 Gm in females and over 450 Gm in males. This increase in weight is due largely to hypertrophy of the left ventricle. There is also some hypertrophy of the right ventricle, because as a general rule when the left ventricle fails the right ventricle hypertrophies in some degree. There is always some dilatation of the left ventricle and frequently of the right ventricle during life, but the left ventricular dilatation may not show up well at autopsy because the left ventricle contracts vigorously at death. In the orthodiagram and the x-ray silhouette made at six feet distance this left ventricular dilatation is nearly always shown.

Some scar tissue is frequently found, especially in the left ventricle. This scar tissue replaces muscle fibers which had previously undergone degeneration. Occasionally one sees small areas of necrosis with leukocytic infiltration. Bacteria have never been demonstrated in such lesions, and Clawson⁶ has shown that this degeneration of the heart muscle and the subsequent scar tissue replacement are practically always found when coronary arteriosclerosis is present. Aschoff⁷ was probably the first to insist that there is no anatomic evidence for chronic myocarditis or true inflammatory processes in the heart muscle in cases of heart failure associated with nephritis and coronary arteriosclerosis. He related the replacement fibrosis to the narrowing of the coronary vessels. Inflammatory infiltration of the heart muscle he found only when rheumatic fever or diphtheria had been present.

Coronary arteriosclerosis of some degree is found in 90 per cent of all hearts of patients dying with hypertension. This is a most important finding because it is a powerful contributing factor in the heart failure that follows high blood pressure and helps to explain the scarring of the myocardium so frequently found in cases of hypertension. As the muscle cell hypertrophies its volume increases faster than its surface, because the surface is proportional to the diameter whereas the volume is proportional to the square of the diameter of the muscle fiber. If the metabolism of the fiber is a function of its volume it is evident that the need for oxygen increases faster than the surface of the muscle through which gas exchange must take place. This may place the heart muscle fiber at a disadvantage so far as supplying its oxygen need is concerned unless an increased capillary circulation is developed. A narrowing of the coronary arteries will lead to a reduced blood flow and a reduced supply of oxygen to parts in need of a greater supply, and eventually the fiber may become atrophic or necrotic and disappear from lack of oxygen. Scar tissue is an indication that a portion of the muscle has disappeared and has been replaced by white fibrous tissue.

In my opinion there is another relationship between hypertension and coronary arteriosclerosis that needs to be emphasized. If the number of hearts with some degree of coronary arteriosclerosis is calculated from Bell and Clawson's 420 cases of hypertension, on the assumption that 90 per cent of all cases show some degree of coronary disease, one finds that there were 378 cases of coronary disease directly associated with

From the University of Minnesota Medical School and the Minneapolis General Hospital.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1935.

1 By essential hypertension is meant high blood pressure not due to glomerulonephritis, congenital cystic kidneys, coarctation of the aorta or hyperthyroidism. High blood pressure includes all systolic pressures over 150 and all diastolic pressures over 90 mm of mercury. The hypertension is the primary pathologic factor. Heart failure, cerebral accident and uremia are consequences.

hypertension In addition, Bell and Clawson's autopsy material showed sixty-nine cases of coronary disease that gave no history of hypertension and the hearts did not weigh enough to be included in the hypertension group But 55.5 per cent of these coronary arteriosclerosis cases showed renal arteriosclerosis It is generally conceded that renal arteriosclerosis is practically never found excepting when hypertension has previously been present From this I conclude that hypertension was present in thirty-eight of these cases of coronary arteriosclerosis Therefore in Bell and Clawson's autopsy material there was a total of 447 (378 + 69) cases of coronary disease, in 416 (378 + 38) of which hypertension was present In other words, 90 per cent of Bell and Clawson's coronary arteriosclerosis material showed evidence of association with hypertension

HYPERTENSION AND CORONARY ARTERIOSCLEROSIS

I have not made a careful and accurate statistical study of my clinical material for information as to the percentage of hypertension present in cases of coronary arteriosclerosis, but a cursory examination of the cards in my index at the Heart Clinic at the University Hospital shows that 83 per cent of all patients had blood pressures over 150 systolic and 90 diastolic Only 50 per cent of the cases of coronary arteriosclerosis were filed directly as coronary arteriosclerosis The other 50 per cent were filed directly as hypertension heart and cross filed as coronary arteriosclerosis The evidence of high blood pressure in the cases filed directly as coronary arteriosclerosis was 67 per cent There is often considerable doubt as to whether a case should be filed as hypertension heart or as coronary disease, and the final decision is somewhat arbitrary The same may also be said of Bell and Clawson's separation of their cases into hypertension cases and coronary cases The remarkable thing is that their anatomic investigation results in the same conclusions as my cursory examination of the clinical records, namely, that coronary arteriosclerosis is associated with hypertension in a very large proportion of cases In his *Textbook of Pathology*, Bell states that 75 per cent of all coronary cases are associated with high blood pressure This agrees well with my analysis giving 80 per cent I think it can conservatively be estimated that 75 per cent of all patients with coronary disease at some time have had high blood pressure

I have been at some pains to emphasize this close relationship of hypertension and coronary arteriosclerosis because I believe it to be of great importance in prognosis and in an understanding of the progress of the disease In patients with hypertension who die of uremia, it is the arteriosclerosis of the small renal vessels that decides the outcome, the state of the cerebral vessels decides the outcome in patients with hypertension who die of encephalomalacia or apoplexy, the fate of the heart in hypertension is also to a very considerable degree decided by the state of the coronary vessels Moreover, it is not infrequently found that the blood pressure falls appreciably and sometimes nearly to normal when an advanced degree of coronary arteriosclerosis develops in a case of hypertension When the patient is seen by the physician the blood pressure may give no evidence of the high values previously present because of the coronary disease and sometimes because of the heart failure Because of their frequent association, hypertension and coronary arteriosclerosis should be considered together

BLOOD PRESSURE

A word must be said about the variability of the blood pressure in hypertension, because it is the high blood pressure that increases the work of the left ventricle and leads to the hypertrophy, dilatation and finally failure of this heart chamber It is rare for the blood pressure to have a steady value in hypertension If one takes the blood pressure from day to day one sees that both the systolic and the diastolic values vary more or less If the patient is put to bed, the blood pressure usually falls some within twenty-four to forty-eight hours In not a few patients with very high blood pressure when up and about, the blood pressure falls to moderate pressures after a few days rest in bed In most persons with hypertension the blood pressure falls somewhat when they are asleep In not a few it falls very considerably and approaches the normal The reassurance of a patient with high blood pressure by a good physician will not infrequently lead to some lowering of the average blood pressure I have already pointed out that the development of coronary disease not infrequently leads to some lowering of the blood pressure Heart failure may also lead to lowering of blood pressure but not invariably There are, however, quite a few exceptions to the general rule that blood pressure in hypertensia varies from day to day and under various external sources of stimulation and under various forms of sedative treatment Many patients retain their high blood pressures despite severe degrees of failure and severe degrees of coronary disease and I have seen pressures of 240/120 up to within one hour of death from severe congestive heart failure

In calculating the work of the left ventricle in hypertensia it is therefore well to keep in mind that the blood pressure falls somewhat during sleep and often during rest in bed Also it is well to keep in mind that the blood pressure often drops not inconsiderably for periods of varying length, thus lessening the fatigue of the left ventricle temporarily The highest blood pressures do not measure the fatigue effect on the left ventricle any more than the lowest pressures do It is the integration of the varying blood pressures over a period of time that measures the effect of hypertension on the left ventricle

It is often said that the diastolic blood pressure is the more important measure in hypertension So far as the work of the left ventricle is concerned, this is not true The work of the left ventricle is measured by the product of the minute volume of blood⁸ and the "mathematical mean" pressure in the root of the aorta during systole When systole sets in, blood is ejected from the left ventricle into the aorta. At the beginning of the ejection the blood pressure in the aorta is the diastolic blood pressure, but within a few hundredths of a second the blood pressure in the root of the aorta rises to the systolic value, at which point it stays as long as blood is ejected from the left ventricle An integration of the blood pressure curve as taken with optical manometers shows that the mathematical mean pressure during the ejection time of the left ventricle is very much closer to the systolic blood pressure than to the diastolic blood pressure, in fact, the blood pressure against which most of the blood is injected into the aorta is very much nearer to the systolic blood pressure than it is to the "arithmetical mean" pressure

⁸ The minute volume is the volume of blood ejected from the ventricle during a minute. In other words it is the volume flow

Therefore the work of the left ventricle in both normal persons and such as have hypertension is approximately proportional to the systolic blood pressures, provided the output per minute is the same.

As the blood pressure rises, so does the work of the left ventricle, however, at first there are no symptoms of fatigue of the left ventricular muscle. The left ventricle must dilate a little according to the "law of the heart" in order to take care of the increased load of

Fig 1—Orthodiagram of heart in case 3. Typical left ventricular dilatation.

work. This physiologic dilatation is only a few millimeters in transverse diameter and is not noticeable on roentgen examination. This physiologic dilatation of the left ventricle takes place at once and is followed later on by a hypertrophy of the left ventricular muscle. Slowly but surely the left ventricle fatigues, and after it has overcome high blood pressure for some years another period of dilatation sets in, which goes on continuously throughout the life of the patient. This dilatation marks the beginning of heart failure. Up to this point there has been compensation for the increased work of the left ventricle through a very slight physiologic dilatation and through hypertrophy. These compensatory mechanisms having failed, increased dilatation must develop.

Even when very high blood pressures prevail, this fatigue dilatation takes place very slowly—usually not as much as 5 mm in transverse diameter in a year, provided there is very little coronary artery narrowing present at the same time. If there is ischemia of the left ventricle consequent to coronary narrowing, this dilatation of the left ventricle takes place more rapidly. As a rule symptoms of congestive heart failure do not develop until there is a very definite left ventricular dilatation present. This left ventricular dilatation produces the typical boot shaped heart (fig 1). Not infrequently the right side of the heart dilates because failure of the left side ultimately increases the work of the right. Moreover, the coronary system to the right ventricle may be narrowing, bringing with it ischemia and failure of the right side. When the right side dilates as well as the left, the x-ray picture corresponds to figure 2. As the heart dilates more and more there are increased signs of congestive heart failure.

SYMPTOMS

Perhaps the first symptom noticed by many patients with a failing heart in consequence of hypertension is an increased tiring at work, a decreased resistance to fatigue. Dyspnea on exertion is also an early symptom.

The dyspnea is consequent to failure of the left ventricle and the accompanying increased venous and capillary pressures in the lungs. Later, rales may appear at the lung bases. As the heart failure increases, edema of the extremities, symptoms of enlarged passive congested liver and cyanosis are added to the symptomatology. Occasionally symptoms of heart failure develop after a severe infection of the upper respiratory tract or other infection. Occasionally severe exertion precipitates heart failure. In some cases the onset of auricular fibrillation brings forth clinical evidence of heart failure. But, even without these precipitating causes, failure of the left side of the heart will eventually develop in all cases of severe hypertension, provided death from some other cause does not intervene before the heart failure develops.

In some cases, attacks of angina pectoris or coronary thrombosis appear. These attacks reveal the presence of coronary disease. Attacks of nocturnal dyspnea are not infrequent in cases of hypertension associated with moderately severe or severe coronary arteriosclerosis. The symptoms of coronary disease may wholly dominate the picture.

Auricular fibrillation is the most common form of arrhythmia found associated with hypertension. When it appears the heart fails rapidly and unless the heart receives competent treatment congestive failure progresses dangerously. Pulsus alternans may be found associated with hypertension some years before congestive failure is present, on the other hand, congestive failure symptoms may come on very shortly after the discovery of pulsus alternans. The electrocardiogram may show only left preponderance or be entirely normal if there is no coronary disease present. The presence of coronary disease is frequently shown on the electrocardiogram by negative Ts, Pardee Q_{III}, depressed ST interval or heart block. On the whole, the symptoms

Fig 2—Tracing of six foot heart plate in case of severe congestive heart failure with blood pressure of 220/110 and electrocardiogram showing evidence of coronary arteriosclerosis. Left and right ventricular dilatation the left predominating.

and signs of congestive heart failure in hypertension are the same as in other forms of heart disease, and when coronary disease is associated with the hypertension the symptoms and signs do not differ from the symptoms and signs in coronary disease not associated with hypertension.

LIFE EXPECTANCY

In my opinion the life expectancy in hypertension is much longer than most physicians are accustomed to believe. I have many patients with hypertension now

under observation who have survived from twelve to seventeen years of very high blood pressure. I am inclined to believe that the average life expectancy is from fourteen to fifteen years. Most persons with hypertension do not come to a physician until symptoms develop, and as a rule such symptoms are not manifest until hypertension has been present for some years. I believe that the short life expectancy found by Blackford in his series is due to the fact that many of his patients had been symptom free with hypertension for years and came to his clinic only after symptoms had developed. Rarely does hypertension produce symptoms of heart failure, renal insufficiency or cerebral disease until it has been present for a number of years. Persons with hypertension are usually vigorous and well for years until the three well known sequelae develop in the heart, brain or kidney. The left ventricle stands up wonderfully under the increased load of work day in and day out. The presence of coronary disease cuts down the time before heart failure intervenes, but even with coronary disease present the left ventricle is equal to its increased task for many years. The following three cases will illustrate this. I do not believe that these cases are very exceptional. I have other cases of high blood pressure of twelve to seventeen years' standing that might have been used for illustration, but these three cases have very full records over a long period of time and in addition the first two have autopsy examinations to supplement the histories.

REPORT OF CASES

Patient 1 was found to have a blood pressure of 220 systolic in April 1912. At that time he was very nervous and showed a trace of sugar in the urine. When he was sent to a celebrated consultant because of the glycosuria, it was discovered that he did not have diabetes but that he had high blood pressure. Since that time he has been examined frequently. His blood pressure has been found as low as 170 systolic on two occasions, once after a long vacation and then in November 1933, a month before he died and at a time when he was resting in bed. His blood pressure was usually found to be from 210 to 230 systolic and from 115 to 130 diastolic. I have found the systolic as low as 190 on a few occasions but a day or two before or after this it would be above 200. The patient was known as a very hard worker. He was active as president of a bank and as president of a merchandising business at the time of his death. He never played golf or took part in organized sports. Yet he was accustomed to walk at a good pace every day up until shortly before he died. In 1925, after thirteen years of high blood pressure, he ran a third of a mile to a fire in a block in which he had his business. Although quite dyspneic, he suffered no other ill effects from this exertion. Only two months before he died he played vigorously with his youngest grandson, following which he stated that he was getting too old for such vigorous exercise and that his wind was gone. He was accustomed to drink wine nearly every day and throughout a large part of his life smoked from eight to twelve cigars a day. The last eight years of his life he noted some shortness of breath on walking rapidly and climbing stairs. His heart showed a slow progressive left ventricular dilatation. Two months before his death the transverse diameter was 16 cm on the six foot heart plate. The transverse diameter for a man of his height and weight is 13.5 cm. Rales were heard at both lung bases and the liver was found just below the right costal margins on several occasions during the seven years preceding his death. Pulsus alternans was found on one occasion about seven years before his death. He fell and fractured his arm in October 1933. He had had one mild stroke a few weeks previously and the fall was undoubtedly in consequence of a cerebral accident. He never recovered after his fall. His sensorium became cloudy and he passed away in November 1933. Autopsy

revealed extensive cerebral arteriosclerosis with moderately extensive encephalomalacia. The lungs showed no signs of edema. The liver was not passively congested on gross examination. The heart weighed 370 Gm and showed very little arteriosclerosis of the coronary arteries. These arteries were wide open on all sections. There was no gross scarring of the muscle. The patient lived twenty-one years with a very high blood pressure. He died from softening of the brain with no demonstrable hypertrophy of the heart muscle and no demonstrable signs of heart failure on gross examination of the organs at the time of his death. He had mild symptoms of heart failure the last seven years of his life but he did not die of heart failure even after twenty-one years of high blood pressure. If he had had moderately severe narrowing of his coronary arteries he would surely have developed severe heart failure and probably would have died many years sooner.

Patient 2 entered the University Hospital in 1917 with a blood pressure of 230/100. She came in because of severe headaches and interstitial nephritis was diagnosed at that time. She was in the University Hospital four times and in the Minneapolis General Hospital four times between 1917 and 1934. During the same period she visited the University Dispensary two or more times every year. Her systolic blood pressure had never been known to be under 200 mm of mercury in all these years. It had usually been from 220 to 230 during the twelve years that I have taken care of her. The diastolic pressure had not been under 100 in seventeen years, and during the twelve years that I have taken care of her it had always been between 110 and 130. My orthodiagraphic examinations showed a slowly progressing dilatation up to 1928. The transverse diameter of the heart was then 16 cm. The normal transverse diameter for her height and weight is 12.5 cm. At this time she had dyspnea on climbing stairs and some pitting edema. In 1932 the six foot plate taken at the Minneapolis General Hospital showed a transverse diameter of 15.9 cm. Moreover she had no clinical symptoms of heart failure any more. She was frequently in bed for long periods from 1931 to 1934 because of her mental condition. This bed rest probably accounts for the recession in heart failure symptoms and in transverse cardiac diameter. In 1930 she had a left hemiplegia and in 1931 symptoms of cerebral arteriosclerosis developed. Her memory became poor, she had transient attacks of aphasia, she was very irritable, and she had many crying spells and often fits of rage. She became very emaciated in 1934 a few months before she died. In 1934 she died. The autopsy revealed a heart weighing 310 Gm. According to the autopsy report of Dr. N. H. Lufkin, there seemed to be a definite hypertrophy of the left ventricle, the thickest portion of it being 2 cm. The left coronary artery in its proximal fourth showed occasional concentric thickening due to atherosclerosis without severe closure of the lumen. After its bifurcation the deeper branch was found to be quite free from thickening of any type while the more superficial branch in the middle fourth and again terminally became rather severely narrowed to half its normal diameter by concentric thickening. The lumen of the circumflex branch was normal in its proximal portion but from its midportion narrowed to one-fourth or one-fifth its normal caliber by concentric thickening. The right coronary artery was concentrically thickened in all portions. Nevertheless it was dilated to nearly twice its normal caliber and even the terminal portions seemed to be of greater than normal capacity. There was moderate patchy fibrosis of the myocardium over the basal portion of the left ventricle posteriorly in the region supplied by the circumflex branches of the left coronary artery. There was one patch of fibrosis near the tip of the left ventricle close to the septum. This was approximately 1 cm in diameter. The kidneys were small and had finely granular surfaces. The cut surfaces showed slight though definite narrowing of the cortices. The brain showed severe diffuse atherosclerosis of all the large arteries at the base. Serial sections of the brain revealed irregular and scattered areas of softening throughout the brain. Autopsy revealed no signs of heart failure, only a moderate degree of arteriosclerotic kidney but a severe degree of focal encephalomalacia, which was the cause of the patient's death.

Patient 3 is now 57 years of age. She was told by her physician in 1919 that she had a very high blood pressure. She had gone to him on account of frequent and severe nosebleeds. In January 1920 she entered the University Hospital, where her blood pressure taken on entrance and throughout a three weeks period of rest in bed was 220/120. On one occasion during the hospital stay the diastolic pressure was measured at 152. She was seen by a private physician for two years, during which time her blood pressure was around 220 systolic and 110 diastolic. I saw her for the first time in 1922 in the University Dispensary. At this time her blood pressure was 240/120. Since then I have seen her at least twice a year, usually much more frequently. Gradually in the course of thirteen years her blood pressure has risen to about 260/140, with some values of 270/150 on the case record. I have had the patient in the University Hospital twice for long periods of observation. Her blood pressure did not fall during sleep. Long rest in bed does not lower it. She has been on an extremely small daily salt intake and on most of the other measures recommended for lowering blood pressure without any effect. In 1928 she had very mild symptoms of beginning heart failure, such as tiring easily and a mild degree of dyspnea on climbing stairs. At this time the transverse diameter of her heart on the orthodiagram was 14 cm. Now in 1935 with a transverse diameter of the heart of 15 cm (Fig 1) and after sixteen years of extremely high blood pressure she complains of considerable dyspnea on climbing stairs. Recently I walked with her at a fair pace and found that she developed little or no dyspnea. She has worked very hard at her housework until the last three years. She still does all her own housework, but this she states is not very hard since her last son left for a home of his own. She notices that she fatigues easily. She has occasional attacks of numbness in the fourth and fifth fingers of her left hand. This numbness radiates up the inner aspect of the left arm to the neck. This angina pectoris equivalent corresponds to an electrocardiogram with a deeply inverted T in lead 3. There are no signs of heart failure, such as rales in the lung bases or enlarged tender liver at this time. There is a very slight edema along the shin bones, but this could easily be explained by the varicose veins that are also present. After sixteen years of very high blood pressure there is only a mild degree of heart failure present and no measurable renal insufficiency.

COMMENT

These patients developed symptoms and signs of heart failure only after many years of high blood pressure. Heart failure might have developed sooner if they had been compelled to perform severe physical exertion. One can see that the frequent periods of bed rest enforced in case 2 after 1931 tended to cause the symptoms of heart failure to disappear and tended to cause a slight reduction in the dilatation of the heart. This shows that decreasing the physical exertion in hypertension tends to prolong the period during which failure is developing. On the other hand, the first patient was known throughout his life as an exceptionally active man and the circumstances of life as well as inclination tended to cause the two women to do more than the average amount of work for an American woman. I think they can be considered average cases in most respects.

TERMINOLOGY

Heart disease consequent to high blood pressure is still called chronic myocarditis by many physicians despite the fact that neither careful clinical study nor competent pathologic investigation gives it any support. I object strongly to this name, because it suggests that infection and inflammation are prominent factors in the production of this form of heart failure, an assumption for which there is no good evidence. In former years, cases of hypertensive heart disease were not infrequently diagnosed mitral insufficiency because of

the presence of the loud systolic murmur that often accompanies dilatation of the left ventricle. This name is also misleading because it suggests that a valvular insufficiency is the cause of the heart failure, whereas relative mitral insufficiency is a result rather than a cause of the heart failure. Other physicians call this condition cardiorenal disease. This name is objectionable because the word renal is equivocal and suggests glomerulonephritis, renal insufficiency, uremia and a host of other factors that may be but usually are not associated with the kind of heart disease I am discussing in this paper. In Munich, where many of the inhabitants drink enormous quantities of beer, this form of heart disease was often called "bier-herz," and in Tübingen it was not infrequently diagnosed "Tübingen wein-herz" when found in a vintner who was supposed to consume quantities of wine and carry heavy loads up the hills where the vineyards are located. There is no justification for any of these names at the present time and it would be well to emphasize the relation of this type of heart disease to hyperpiesia by terming it "hypertensive heart disease" or "hypertension heart."

TREATMENT

The therapy of the heart in hypertension does not differ from the therapy of congestive failure of other origin. I have treated this subject quite thoroughly in a previous paper and will refer to that paper for a discussion of the therapy of the heart in hypertension. At present I am inclined to use somewhat larger doses of theophylline ethylenediamine or aminophylline to dilate the coronary arteries than were recommended in that paper, 0.2 Gm four times a day being the usual amount that I now prescribe.

CONCLUSIONS

- 1 Fifty-five per cent of the appalling death rate consequent to essential hypertension is due to heart failure. Moreover, heart failure of some degree is nearly always present in cases of essential hypertension in which death occurs in uremia or from apoplexy or cerebral softening.

- 2 The heart in hypertension shows left ventricular hypertrophy and dilatation with varying grades of replacement scarring in the muscle. There is some coronary arteriosclerosis present in 90 per cent of the cases. The coronary narrowing is responsible for the scars found in the heart muscle.

- 3 A very high percentage of patients with angina pectoris and coronary arteriosclerosis have high blood pressure complicating the cardiac picture.

- 4 Hypertension and coronary arteriosclerosis are so intimately and frequently associated that they should be considered together and the term "hypertensive heart disease" or "hypertension heart" should connote coronary involvement.

- 5 What has been termed "chronic myocarditis" is usually the result of high blood pressure and coronary artery disease and not the result of infection.

- 6 Heart failure in the clinical sense does not develop in hypertension until many years (from ten to twelve) have passed unless the coronary disease accompanying the high blood pressure becomes very severe or unless some other cardiac complication is present. Many patients with hypertension live fifteen years or more and finally die of one of the other consequences of hypertension, though some degree of heart failure may have been present previously or at the time of death.

THE REHABILITATION AND PLACE-
MENT IN INDUSTRYOF THOSE HANDICAPPED WITH CARDIOVASCULAR
DISEASEWILLIAM D STROUD, MD
PHILADELPHIA

Owing to the results of the World War, organization for training the handicapped and placing them in industry of necessity has progressed much more rapidly in Europe than in this country. In most European countries, during the past seventeen years, it has become a national obligation. In Germany they have gone so far as to regulate legally the training and placing of the handicapped, demanding that 2 per cent of all positions in various industries must be filled with individuals at least 50 per cent disabled.¹ I first became interested in this problem while working in England during the years of 1919 and 1920. One day at luncheon, Sir Thomas Lewis remarked that "in the ideal state, no position in industry which might be filled by a person handicapped with cardiovascular disease should be filled with an entirely healthy individual." This, of course, is a strong statement but is certainly worthy of careful consideration.

The majority of the handicapped who may be rehabilitated and placed in industry are those with cardiovascular, arthritic and orthopedic disabilities. Various studies of the numbers of handicapped individuals and vital statistics would suggest that by far the largest group of such handicapped individuals trainable and available for industry is the cardiovascular group.

One of the first and most practical steps in planning for the training and placement of those handicapped with cardiovascular disease was the advocacy of a functional classification of cardiac patients that might be practical from the standpoint of the social service worker, those administering state and city rehabilitation bureaus, and employers in industry. The Heart Committee of the New York Tuberculosis and Health Association has recommended the following functional classification of patients with organic heart disease.²

Class I Patients with organic heart disease, able to carry on ordinary physical activity without discomfort.

Class II Patients with organic heart disease, unable to carry on ordinary physical activity without discomfort

A. Activity slightly limited

B. Activity greatly limited

Class III Patients with organic heart disease, and with symptoms or signs of heart failure when at rest, unable to carry on any physical activity without discomfort.

Class E Possible heart disease. Patients who show abnormal signs or symptoms referable to the heart but in whom the diagnosis of heart disease is uncertain.

Class F Potential heart disease. Patients without circulatory disease whom it is advisable to follow up because of the presence or history of an etiologic factor that might cause disease.

The greatest difficulty in such a movement is the fear in the minds of the employers as to the result of the workmen's compensation act and the possible draining of sick benefit funds, if cardiac patients are given work and then break down in their employ. It is

notoriously difficult to state positively that almost any occupation may not have contributed in some slight degree to the progression of a cardiovascular lesion that has finally ended in heart failure or sudden death. During the past few years I have given expert testimony in such cases before a compensation board referee and I have been impressed with the marked difference in various states as to the standards on which compensation board referees make their decisions as to the relationship of cardiovascular disease to sudden death. In Pennsylvania a man while filling a bucket at a marble hopper suddenly fell, striking his head on the edge of the marble hopper. He died within a few minutes and the coroner's diagnosis as to the cause of death was coronary thrombosis. The family was awarded compensation for accidental death, since the referee decided that if the man had not struck his head against the marble hopper as he fell, the coronary thrombosis might not have killed him!

* This table was compiled by the Metropolitan Life Insurance Company of New York.

† Death rates from all causes are per thousand of population.

‡ Death rates from tuberculosis and other causes except diarrhea are per 100,000 of population.

§ Death rates from diarrhea under 5 years of age are based on the population under 5.

In the District of Columbia a man who for many years had placed fruit on a display stand of a fruit store and piled potato sacks in a corner developed a pain in his chest while lifting one of the potato sacks. He went home and went to bed. A few days later he developed evidence of congestive heart failure. A physician examined him and found a plus four Wassermann reaction, evidence of syphilitic cardiovascular disease with aortic insufficiency and congestive heart failure. Six months later the patient died, never having sufficiently recovered to arise from his bed. The referee awarded compensation to the family, since he decided that the lifting of the potato sack was a contributing factor in the development of the heart failure, in spite of the fact that his work the day of the so-called accident was no different than on any other day during the past few years.

In West Virginia a mule driver in a mine helped his mule by pushing a small coal car over a small incline. A few minutes later he developed an agonizing epigastric and anterior chest pain. He died a few minutes later, and the coroner's diagnosis as to the cause of death was coronary thrombosis. The compensation

This work has been done through the Robinette Foundation of the University of Pennsylvania and the M. W. Stroud Jr. Fellowship in Cardiology of the Pennsylvania Hospital.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1935.

1 From an unpublished report by Mr. Sherman C. Kingsley.
2 Adopted and distributed by the American Heart Association, Inc., 50 West Fiftieth Street, New York.

board referee decided against awarding compensation to the family, since helping the mule at times was part of his ordinary duty in the place where he worked.

Until there is some uniformity in the workmen's compensation act in the various states, and some uniformity in the interpretation of the act by the various

Fig 1—A. L. aged 9 years. Home education. Rheumatic fever (arthritis), enlargement of the heart, mitral stenosis and insufficiency aortic insufficiency sinus arrhythmia, class 2B. This little girl went to school for only two days. Later she was taught in the Children's Heart Hospital. She was not able to return to school and when the visiting teacher made her first contact she found a 9 year old child who could read only at the first grade level and could not do better than 2A work in any subject. She had a great fear of returning to school because she was so far behind. In five months she has completed a year's work in the fundamental subjects and looks forward with pleasure to returning to school next September. Referred by Philadelphia Heart Association.

referees and courts, it will be a difficult matter to persuade employers to accept individuals handicapped by cardiovascular disease.

During the past twenty years the medical profession has learned that, in spite of valvular disease, many individuals can perform the average type of work without materially impairing their health or shortening their lives. The realization by the medical profession that infections appear to play a larger part in cardiac failure and the progression of cardiac disease than does physical effort should aid in the placement of cardiac patients in industry, if this impression, through public

health education, can be passed on to the employer and the general public.

TRAINING IN SHELTERED WORK SHOPS³

In the sheltered work shop of the Philadelphia branch of the Shut-In Society and Vocational Adjustment Bureau for the Handicapped, which is financed by the Welfare Federation of Philadelphia, in three years' time

Fig 2—W. C. C. aged 60. arteriosclerosis cardiac enlargement and coronary sclerosis normal sinus rhythm class 2B. This man was a World War veteran and was unable to procure employment for many years. He had vocational training at home for several years before his death. The occupational therapist trained him to make hooked rugs. He became quite an expert at this and the organization was able to dispose of them for him.

there have been twenty-six persons with heart conditions classified from 2A to 2B. They worked at carpentry, machine and hand sewing, upholstery, and general work about the place.

In the machine and hand sewing department there were ten who worked six hours a day. They were paid

³ Statistics supplied by Miss Ann Laws Calley, executive secretary of the Philadelphia branch of the Shut-In Society and Vocational Adjustment Bureau for the Handicapped.

from 75 cents to \$1.68 a day and furnished milk for lunch. In the woodworking and upholstery departments fifteen persons worked from three to five days a week from five to seven hours a day. One worked at part time cleaning. They received from \$1 to \$2.80 a day. These persons accomplished a good normal day's work in these departments. There were no deaths and no accidents while at work. In a year two persons, both women, fainted and were treated in the rest room. Of these twenty-six cardiac patients, two have died as a result of their heart condition, but this was at home under ordinary circumstances. We have not been successful in placing any cardiac patients in industry through the Rehabilitation Bureau, but this I believe is due to the inefficiency of the local bureau and the present unemployment situation.

One patient who worked in the shop had progressed into a fine full time worker. Owing to lack of work she was placed on part time. With this extra time at home, she tried to take on the activities of other girls of her own age and is now in the hospital with a reaction of her rheumatic fever.

One hundred and ninety-five persons with heart conditions are known to our organization. Of this number

Fig 3—N. D. aged 19. rheumatic fever cardiac enlargement and mitral insufficiency normal sinus rhythm class 2A. Began working in the woodworking department seven hours a day Oct. 31, 1934 at \$5 a week. Total wages \$53.58. Total time worked three months. This young man is the only one employed in his family. He was very eager to work even though it was not possible to pay him a larger salary. He was very much interested in the work and did it very well.

fifty-seven could be employed if work were available, fifty are not employable and eighty-eight are under 16 years of age.

PLACEMENT OF CARDIAC PATIENTS IN EMPLOYMENT⁴

The placement of cardiac patients in suitable employment was carried on successfully from 1926 to 1932 by the Philadelphia Heart Association through a cooperative arrangement with the Philadelphia Health Council and Tuberculosis Committee. The entire placement service included persons with arrested tuberculosis as well as heart patients, but I shall speak only of the heart patients who were placed.

During the seven years from 1926 to 1932 a total of 280 heart patients were placed in employment, some of them more than once, so that a total of 388 jobs were filled by these patients. During the first three years of this service, no effort was made to ascertain the amount earned by the cardiac patients who were

⁴ Statistics supplied by Mr. Harvey Dee Brown, executive secretary of the Philadelphia Health Council and Tuberculosis Committee.

placed. But from the years 1929 to 1932 the earnings of heart patients placed by the service amounted to upward of \$90,000.

During the time of the service twenty-two heart patients were placed in training, fifteen of whom had completed the training or were still carrying it on in December 1932. This work was then transferred to the State Bureau of Rehabilitation in 1933 and is being continued by the bureau.

The applicants for placement were referred from the twenty-one heart clinics of Philadelphia and by private physicians. Each applicant had a medical examination and a diagnosis card filled out by the referring physician. The diagnosis included etiologic, anatomic and physiologic factors, a functional classification and an indication of the work tolerance of the applicant in terms of the activities he would normally undertake. A statement of the applicant's limitations regarding stair climbing, standing, stooping, weight lifting and walking was included. In addition to this report, each applicant was studied individually by the social service worker in charge of this placement service, as to his employment history, his mental attitude and his abilities as a worker. Each presented an individual problem.

Finding employment for the applicants required persistent interviewing of employers. All sections of the city were included so as to place the applicants in work near their homes and reduce travel if possible. In order to get an idea of safe jobs in factories, as well as of the physical conditions existing in the plant, visits were made to various parts of the plants.

Few employers desire persons below par physically even for the simplest jobs. All placement work of handicapped persons requires persistent solicitation of the employers. They must be told that persons whose physical condition has been determined by an examination can be placed in suitable work and prove to be a definite asset. It is pointed out also that physically

Fig 4—J. T. a cardiac patient engaged in machine and true hand sewing. Referred by the Pennsylvania Hospital. Rheumatic fever, cardiac enlargement, mitral insufficiency, mitral stenosis, regular sinus rhythm, class 1.

handicapped workers, when properly placed, are usually permanent and faithful, since they appreciate having a job. The fact that a continuous follow up after placement is stressed which insures that the worker will not be allowed to remain on the job unless he can safely do so is pointed out. These arguments ordi-

narily reduce the employer's objections. Often after a handicapped person has been placed and proves to be a successful worker, calls are made for another handicapped worker.

A single illustration from the records of this service shows the value of this work. Rocco C. is a boy who had started to learn the plumber's trade. As it involved

Fig 5—R. B. aged 50 years, a cardiac patient engaged in wood working. Rheumatic fever, mitral stenosis and insufficiency, normal sinus rhythm, class 2A.

a great deal of physical strain, which was showing its effect on his damaged heart, his physician insisted that he give it up. After Rocco had been seen and some idea of his capabilities had been obtained, he was sent to talk with the superintendent of a leather goods factory. This factory makes high grade leather purses, hand bags and toilet cases. Although the superintendent had said he would not be able to take on any beginners then, after talking with Rocco he employed him to begin the following day. Since then Rocco has had his troubles at home, as his father was out of work for some time, and much pressure was brought to bear to make him leave and get a job paying more money. This, however, he refused to do. Rocco has since had a raise, and the superintendent reports that he takes an interest in his work and is getting along nicely. Rocco's frequent correspondence corroborates this statement. His physical condition is satisfactory as reported by the clinic physician.

POSSIBILITIES FOR EMPLOYMENT IN INDUSTRY⁵

In the study of employment possibilities for the physically handicapped in Philadelphia industry, the occupations suitable for general cardiac patients have been defined by the following restrictions:

Generally good working conditions as to ventilation and comfort, without special hazard of materials, machinery, electricity and so on.

Light work requiring no rapid movements of the body.

A minimum of nervous tension such as may be attendant on intensive production methods or the operation of high speed machinery.

⁵ Statistics supplied by Mr. F. W. Steuber working for the Philadelphia branch of the Pennsylvania State Bureau of Rehabilitation.

COMMENT

No subdivisions of cardiac cases have been considered. It appears that the restrictions of work as given are sufficient to allow for the majority of patients not actually unemployable.

It will be noted that this study is not primarily concerned with the individual's disability but with the jobs that can be performed by the general class of those so handicapped.

TABLE 2—*Vocational Possibilities for Heart Patients*

| Skilled Labor | |
|---|--|
| Woodwork | Electrical construction |
| a Cabinet making | a Wiring signs |
| b Novelty—small toys jig saw puzzles, bag tops small weaving frames | b Radio work |
| | c Assembling electric cords and the like |
| Textiles | Mechanical drafting |
| a Chemistry | a Making and filing blue prints |
| b Weaving | b Architectural planning |
| c Designing | Commercial art |
| Commercial work | a Advertising |
| a Stenography and typewriting | b Poster making |
| b Filing and indexing | Designing |

| b Labeling | |
| c Sorting slips | |
| d Folding posters | |

* If a factory has signed an NRA code it may not employ any children under 16 but the labor law has not yet been changed.

In the pursuance of this study, 40,000 workers have been more or less directly observed in the performance of 1,000 different operations in twenty-five industries. Since these operations at present employ as many more workers not observed and the total grows to 115,000 in normal times—about half of the 200,000 odd normally employed in manual work in Philadelphia industries, when common labor and the higher brackets have been excluded—the coverage is considered sufficient to represent the whole. The data gathered during the study of these operations from the standpoint of performance of the specifically handicapped has been tabulated on the basis of possibilities per thousand workers in each industry. For the cardiac classification, the data are given in table 3.

The large variations among the industries reflect primarily the differences in the character of the work. In some cases, notably hat and cap manufacturing, the influence of a strict medical examination of employees is paramount. It must also be admitted that the individual making the study has had an influence in some cases, though these men have all been engineers with industrial experience.

A number of other industries have been covered without tabulations having been made. The general

showing bears out the figures of the tables, indicating that 25 per cent of all jobs in industry are possible of performance by this class of handicapped person without compromising either the job or the job holder.

CONCLUSIONS

1 Vital statistics suggest that individuals with cardiovascular disease comprise as large a group, if not the largest group, of persons with physical handicaps.

2 It seems questionable whether physical effort is responsible for the production of cardiovascular disease or plays as large a part in the progression of cardiovascular disease as has been previously believed. If this is true, the training of cardiac patients and their placement in industry constitute as great a responsibility for the physician as any other form of therapeutics—in fact, in class 1 and 2A cases a much more important responsibility than medication or other forms of therapy.

3 With proper functional classification by private physicians or physicians in heart clinics, with especially trained placement workers in city and state rehabilitation bureaus, cardiac patients in much larger numbers than previously recognized may earn a living through

training in sheltered work shops with ultimate placement in industry, or, if previously trained, through direct placement in industry.

4 If common labor is divided into two classes, namely, light labor and heavy labor, almost 100 per cent of cardiac patients, except those in class 3, are employable at light labor.

5 To accomplish such rehabilitation and placements, it is necessary to obtain the interest of the medical pro-

fession and to impress physicians with their responsibility toward the handicapped, and the necessity of cooperating with the social service workers, especially trained placement workers and city, state and county rehabilitation bureaus. Employers should be carefully approached and educated. Finally, and perhaps most important of all, is the sympathetic handling of the unfortunate individual handicapped by cardiovascular disease.

1011 Clinton Street

A CRITICAL ANALYSIS OF HEART DISEASE MORTALITY

O F HEDLEY, MD

Passed Assistant Surgeon, U S Public Health Service
PHILADELPHIA

The statement that heart disease is the leading cause of death has become almost axiomatic. Despite the voluminous literature that has been developed regarding heart disease mortality, most of the writers have been uncritical of the sources from which such information is obtained and of current practices in compiling vital statistics. My purpose in this article is to discuss frankly the accuracy with which deaths from cardiac diseases are reported and to appraise present-day methods of computing heart disease mortality statistics. I shall show that the official system of tabulating heart disease mortality is not keeping pace with well established advances in clinical medicine and offer suggestions for improving it.

HOW ACCURATE ARE HEART DISEASE MORTALITY STATISTICS?

To determine the present status of heart disease mortality statistics, a study was made of deaths attributed to heart disease in Washington, D C, during 1932 by analyzing death certificates filed in a routine way throughout the year. It was obviously impossible to ascertain the accuracy of the entire number of deaths listed as being due to heart disease. Through the courtesy of every hospital in the city, permission was obtained to review intensively the clinical records not only of fatal cases officially recorded as heart disease but also of deaths listed under other titles, to determine the possibility of heart disease playing a role in the fatal termination. It is with the deaths occurring in hospitals that this paper will largely deal, although references will be made to deaths attributed to heart disease occurring in the city at large.

There were all together 1,631 deaths listed in the office of the registrar of vital statistics as being due to heart disease, 416 of which were reported from hospitals (table 1). In sixty-six instances the clinical records could not be used because of insufficient evidence, these described deaths occurring en route or within twenty-four hours after admission. There remained 350 deaths attributed to heart disease with clinical records sufficiently complete to determine whether the deaths were due to heart disease, and, if so, the etiologic factors in most cases.

On review of the records it was found that in seventy-one instances, or slightly over 20 per cent, the clinical records indicated that the cause of death was due to conditions other than heart disease. Of the deaths recorded as heart disease but found to be due to other diseases pulmonary tuberculosis occurred most frequently, cerebral hemorrhage came second and malignant conditions third (table 2). Of these seventy-one deaths the actual cause was determined by necropsy in thirty-four instances. It should be noted that the list included no deaths from senility or borderline cases of nephritis or similar conditions in which the cause might reasonably be considered due to heart disease or to the other condition.

The etiologic factors involved in these 450 fatal cases of heart disease included arteriosclerosis and hypertension in 61.4 per cent, rheumatic infection (active and inactive) in 13.3 per cent, syphilis in 12.0 per cent, bacterial endocarditis and pericarditis in 4.7 per cent, congenital malformations in 2.0 per cent, thyrotoxicosis in 1.3 per cent, cor pulmonale in 0.4 per cent, tuberculous pericarditis in 0.2 per cent and undetermined etiology in 4.7 per cent. These percentages approximate quite closely those of numerous other workers dealing with both clinical and necropsy material. A more detailed account of these observations with special emphasis on the differences in etiologic factors in the races and sexes has been made the subject of another article now in course of publication.¹

The extent to which heart disease mortality was recorded as heart disease varied considerably with the different etiologic categories. Only 64.5 per cent of the arteriosclerotic-hypertensive forms of heart disease were so tabulated. Of the deaths from rheumatic heart disease, only 60 per cent were so listed. Of the deaths from syphilis of the thoracic aorta and heart, only 51.8 per cent were included under heart disease. The deaths from subacute bacterial endocarditis were recorded as heart disease in 85.7 per cent of instances, the highest of any etiologic type (table 3). None of the nine deaths from congenital heart disease were incorporated into the mortality statistics as heart disease, and only one of five deaths from thyrotoxic heart disease was so tabulated.

Furthermore, there was no relation between the etiologic factors and the recorded causes of death. Thus, of the forty-eight deaths attributed to chronic endocarditis, nine were due to arteriosclerotic changes, twenty-one to rheumatic infection, thirteen to syphilis, four to bacterial endocarditis, and one to heart disease of undetermined etiology. With the present system of tabulating heart disease mortality an attempt is made to group arbitrarily quite dissimilar clinical and pathologic conditions. The result is that, in each of the titles and subtitles into which deaths from heart disease are catalogued, diseases are included that have no relation to one another.

Referring to table 3, it should be noted how frequently deaths from heart disease are recorded as due to the conditions etiologic of it. This is due to the trend toward diagnosing heart disease along etiologic lines. If mention is made on death certificates of causative factors, they are not tabulated as heart disease, if reported as organic heart conditions, no consideration is given the various underlying infections and metabolic disturbances.

Published by permission of the Surgeon General.
Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Sixth Annual Session of the American Medical Association Atlantic City N J June 14 1935.
This study was made while the author was stationed at Washington D C, and will be described in greater detail in a Public Health Service bulletin entitled *Studies of Heart Disease Mortality*. More definite recommendations are made in the forthcoming bulletin.

¹ Hedley O F. The Etiology Race and Sex of 450 Fatal Cases of Heart Disease Occurring in Washington (D C) Hospitals During 1932. Pub Health Rep to be published.

EXPLANATION OF THE UNSATISFACTORY STATE OF HEART DISEASE MORTALITY STATISTICS

The reasons for the unsatisfactory state of heart disease mortality statistics are fourfold (1) mistakes in signing death certificates, (2) weaknesses inherent in the present system of recording heart disease mortality, (3) misinterpretations and lack of competent professional supervision in offices of vital statistics, and

TABLE 1—*Sources of Material and Extent of Errors in Recording Hospital Deaths from Heart Disease, Washington D C, 1932*

(4) the theory that a definite cause should be assigned to each death, even though the knowledge of the case does not warrant it

The accuracy of any system of vital statistics depends on the diagnostic skill and care used by the practicing profession preparing death certificates. In the matter of reporting mortality, heart disease may be called "the Great Convenience." The idea seems to prevail in many quarters that "when in doubt call it myocarditis." Without attempting to minimize the significance of heart disease as a clinical or public health problem, the fact nevertheless remains that many diagnoses of heart disease are made without an adequate factual basis.

The main reason for this is that death occurs in many conditions other than heart disease after varying degrees and duration of congestive heart failures. Consequently attention is focused on the heart during the terminal stages of many diseases not primarily cardiac. The family of the patient is informed that the heart is weak, consultations are not infrequently held, and medication is administered to maintain the heart action. This is justifiable from both humanitarian and therapeutic points of view. The trouble is that, when death occurs, undue emphasis is placed on the heart in signing the death certificate. It should be remembered that, while cardiac failure is clinically easily detectable and to a certain extent combatable, other organs show evidence of agonal failure. One shudders to think of the number of contested wills and other forms of litigation that would result if diagnoses of encephalopathies or mental insufficiency were made as frequently in cases showing terminal clouding of the sensorium as diagnoses of myocarditis or myocardial insufficiency are now made.

Heart disease is not infrequently purposefully assigned as the cause of death from other conditions. This is especially true in the South, where certain insurance companies with Negro policyholders refuse to pay benefits on deaths due to tuberculosis and syphilis. Deaths from such conditions or malignant growths are sometimes reported as heart disease

to save the feelings of the bereaved family. There is also too great a tendency to report deaths as due to heart disease when the exact cause is not known. In general, heart disease is a "safe" diagnosis, one frequently expected and not often questioned by members of the family, bureaus of vital statistics, or insurance companies.

Owing to the necessity of filing death certificates prior to moving a body, they are sometimes hastily prepared. It often happens in hospital practice that after the death certificate has been completed permission for necropsy is obtained. The actual cause of death is determined but the death certificate is not corrected. This has been overcome in some places by requiring the pathologist as well as the clinician to certify the cause of death in cases in which postmortem examinations are held.

Many of the terms used in ascribing causes of death are indefinite or obsolete. Thus, of the seventy-one deaths listed as heart disease but found on examination of the records to be due to other causes, the diagnoses in fifty instances were myocarditis, myocardial degeneration or myocardial insufficiency, while only three were diagnosed along etiologic lines. While the use of an etiologic basis is not suggested as a panacea for all mistakes in diagnosis, the use of correct terminology implies greater accuracy of thought, or at least a more comprehensive knowledge of the subject. Certainly the converse seems to apply. Mistakes are more common when inexact or antiquated terms are used.

Some physicians appear to have faith in the adage that there is strength in numbers. A total of 3,506 diagnostic expressions relating to heart disease were used in describing 1,631 deaths. Not infrequently three items were found on a death certificate. Some con-

tained as many as six. Many of the terms used were nearly synonymous. Others were descriptive only of symptoms, signs or terminal events. It is difficult to see what place such terms as dyspnea, ascites, edema, heart failure or cardiac asthma have on death certificates, either as primary or as contributing causes. The routine use of multiple diagnoses is cumbersome and makes the adjudication of the cause of death extremely difficult. It would be far better to describe a death as "rheumatic pancarditis" than as "endocarditis, myo-

carditis and pericarditis," or as "hypertensive heart disease" rather than as "myocarditis, cardiac enlargement, high blood pressure and cardiac asthma."

While errors and laxities in diagnosis constitute more than a mote in the eye of the practicing profession, it is not a beam of such magnitude as that in the eye of those entrusted with the collection and tabulation of mortality statistics.

The International List of Causes of Death² was promulgated in 1853 during a period when interest centered around the discovery and clinical interpretation of organic lesions. Although the product of many revisions, the present list, prepared in 1929, is a not dissimilar elaboration of the first one. Heart disease mortality is tabulated under pericarditis, endocarditis, myocarditis and diseases of the myocardium, angina pectoris and diseases of the coronary arteries, and other diseases of the heart. The chief difficulty is that

of the American Heart Association, and some form of etiologic classification, usually that of the American Heart Association, is used by practically all of 250 other cardiac clinics not affiliated with that organization.⁵

The etiologic classification of heart disease has recently received a further impetus by the inclusion of the American Heart Association nomenclature in the Standard Nomenclature of Disease⁶ prepared in 1933 under the auspices of the Commonwealth Fund. Copies have been sent to about 550 hospitals. One hundred and fifty institutions are known to have adopted it and it is believed that about 300 are now using it.⁷ Most of the university hospitals in the country have already adopted this classification.

The Office of Heart Disease Investigations of the Public Health Service sent questionnaires to 1,400 hospitals inquiring about the use of etiology in their classification of diseases. Of 1,000 thus far reporting,

heart disease is no longer thought of clinically in terms of structural diagnoses but along etiologic lines. It is impossible to interpret satisfactorily etiologic diagnoses in terms of the International List of Causes of Death. This, together with improvement in diagnosis, results in a continuous ebb and flow of deaths computable as "organic diseases of the heart" and a constant realignment of diseases tabulated under this heading. It is doubtful whether mortality statistics from heart diseases in one decade closely parallel those of another.

Etiology is the basis of modern clinical diagnosis. This developed from the observation by Cabot³ in 1914 that most heart disease was due to arteriosclerosis, rheumatic fever, syphilis and thyrotoxicosis. Since then a number of etiologic classifications have been devised, notably that by the Heart Committee of the New York Tuberculosis and Health Association and now sponsored by the American Heart Association.⁴ This nomenclature is now in use in the ninety-six member clinics

nearly 500 indicated the use of some form of etiologic nomenclature.

This emphasis on etiology is no passing fad. It is being incorporated into the standard textbooks not only on heart disease but on general medicine. Practically every medical school in the country is teaching heart disease from this point of view. It reflects a real advance in clinical concepts and will probably be the permanent basis for cardiac diagnosis.

Certain deaths previously tabulated under other categories are now considered due to heart disease. At one time it was thought that most deaths associated with arterial hypertension were due to nephritis. Now many of these are grouped under heart disease. Deaths previously attributed to senility are now listed as heart disease. "Acute indigestion" is a thing of the past. Only three such deaths were listed among 7,949 deaths in Washington, D C, during 1932.⁸ Most

of such cases are recognized as coronary thrombosis. On the other hand, there has been a splitting off of deaths formerly listed under organic diseases of the heart but now diagnosed along etiologic lines. Deaths previously diagnosed as aortic insufficiency and listed as heart disease are now diagnosed as syphilitic heart disease and tabulated not under heart disease but as syphilis. Deaths from acute rheumatic carditis are recorded under title 56, "rheumatic fever," as though the joint and not the cardiac manifestations were the cause of death. Deaths from the more chronic forms of rheumatic heart disease, while recorded as heart disease, are placed in various titles and subtitles, depending on the slightest variation in the wording of death certificates. If diagnosed as "rheumatic valvular disease," deaths are considered due to endocarditis, while, if diagnosed as "rheumatic heart disease," they are tabulated under "other diseases of the heart." Congenital heart disease is tabulated as a separate subtitle under congenital malformations. Thyrotoxic heart disease is recorded under various forms of goiter, while the myxedema heart is listed under myxedema.

Within the group of diseases listed as "organic diseases of the heart" there is a constant change in interpretation. Halsey⁹ pointed out that from 1922 to 1926 in New York state deaths reported as chronic myocarditis increased from 34.1 to 48.6 per cent of the total recorded mortality. During this period, deaths from valvular diseases decreased from 23 to 15.7 per cent. During that period the profession was "myocardially minded." Since then it has become more fully recognized that in many cases the functional ability of the myocardium depends on the state of the coronary arteries and that coronary arteriosclerosis not infrequently results in death from congestive failure without coronary thrombosis or the anginal syndrome. Consequently, another shift is now in progress. As it is generally observed that diagnoses based on etiologic conceptions tend to be made more uniformly, it is believed that the use of an etiologic basis for computing mortality statistics would serve as a balance wheel against fads and fancies in diagnosis.

To enable registrars of vital statistics to determine which of two or more diagnoses occurring on a death certificate is to be assigned as the cause of death, a manual of joint causes of death has been prepared. The necessity for such a manual becomes apparent when it is considered how frequently multiple diagnoses are made. Many of the rulings contained in this manual appear to be highly arbitrary. For example, nephritis takes precedence over heart disease if the two are mentioned jointly on a death certificate. Thus, if nephritis is listed as a secondary diagnosis while the primary cause of death is rheumatic heart disease or subacute bacterial endocarditis, the cause of death is officially attributed to nephritis.

This system of selecting the outstanding diagnostic factors becomes even more involved when only the diseases of the heart are considered. Chronic myocarditis is given precedence over diseases of the coronary arteries, although in reality the myocardial changes are secondary to those in the coronary arteries. Angina pectoris, on the other hand, is favored over chronic myocarditis. Chronic myocarditis is preferred over acute endocarditis but is regarded as less significant than chronic endocarditis. Angina pectoris takes preference over diseases of the coronary arteries,

despite the fact that angina pectoris is generally considered due to coronary insufficiency. It was found that in Washington, D. C., during 1932 angina pectoris was mentioned on seventy-two death certificates, as the primary cause of death in only fifty-eight instances, but was the recorded cause of sixty-eight deaths. Coronary thrombosis was listed on 259 death certificates, on 144 of which as the primary cause of death, but only seventy-eight deaths were officially ascribed to diseases of the coronary arteries. This lack of correlation between the reported causes of death and the official tabulation occurred in practically each title and subtitle included under "organic diseases of the heart."

Not infrequently death certificates diagnosed according to approved and widely accepted methods are returned to physicians for correction largely because of difficulties in interpreting such diagnoses in terms of the International List of Causes of Death. For example, hypertensive heart disease is frowned on as a cause of death, yet it is a condition recognized in modern textbooks¹⁰ and by the American Heart Association.⁴ I have seen diagnoses of hypertensive heart disease made in university hospitals in two cities returned for correction and have had cardiologists of nation-wide reputation tell me of the difficulties in having their diagnoses accepted by offices of vital statistics. This places a premium on incorrect diagnoses or the use of obsolete terminology and is not playing fair with the profession.

Apropos the last paragraph, one of the chief sources of error is due to lack of competent professional supervision in offices of vital statistics. It was found that in Washington, D. C., diagnoses of coronary thrombosis were recorded under heart disease while those of coronary occlusion were tabulated under diseases of the peripheral arteries. It is doubtful whether any health department is so understaffed that death certificates cannot be reviewed by a graduate in medicine. Under no circumstances should the lay personnel be permitted to challenge physicians' diagnoses.

One of the chief hindrances to better mortality statistics of heart disease is the fallacious idea that death certificates must necessarily contain some precise cause of death, even though the facts of the case do not warrant it. This is especially significant with regard to coroners' cases and other forms of sudden death. While most sudden deaths are due to heart disease, this is not always the case. Many such diagnoses are made on very meager knowledge. This is not always the fault of the coroners, as in several states they are not permitted to hold necropsies except when there is presumptive evidence that death is due to intentional violence by some other person. In many localities, coroners are not given sufficient funds to hold necropsies except in cases with medicolegal implications. It is suggested that greater latitude be given in such cases and that diagnoses of "sudden death due to natural causes" be permitted more frequently. This also holds for deaths from natural causes occurring in private practice, when the physician does not know and cannot determine the exact cause.

SUGGESTIONS FOR IMPROVEMENT

The current system of compiling heart disease mortality is entirely out of step with modern clinical concepts. The anomalous situation exists that, within certain limits, the more accurately heart disease is

reported the greater will be the difficulties of interpretation in terms of the International List of Causes of Death. Unless revised, it will eventually become a sort of statistical anachronism.

The International List of Causes of Death was devised for the purpose of obtaining relatively uniform vital statistics throughout the civilized world. In most cases it serves a useful purpose. It is recognized by law and treaty agreements. There is no possibility of replacing this system or even of materially altering it prior to the next decennial revision in 1940. At the next meeting of the International Commission, serious consideration should be given plans whereby heart disease mortality may be tabulated along lines in keeping with approved clinical practices. Incidentally, it would be interesting to learn to what extent heart disease is being reported along etiologic lines in other countries.

Meanwhile there are several steps which can be taken to improve heart disease mortality statistics. Physicians should be encouraged to report deaths from heart disease from the point of view of etiology. Descriptions of organic lesions and of significant physiologic changes should be made with and after the etiologic diagnosis. In the matter of tabulation, however, the entire diagnosis of heart disease should be considered as a unit. This could be accomplished by giving the etiologic diagnosis greater weight than other factors in the Manual of Joint Causes of Death.¹¹

The profession is urged to diagnose as heart disease only those deaths in which there is manifest evidence of heart disease as determined by the clinical course, history and laboratory evidence of established etiologic factors, and the finding on physical examination and at necropsy of organic cardiac lesions. The implication of the heart in cases of terminal congestive failure due to other causes is to be deprecated. Diagnoses should be made with an exactness of terminology commensurate with the knowledge of the cases. Physicians, especially coroners, should be permitted greater latitude in ascribing deaths to natural but ill defined causes when the facts do not permit greater exactness. It should be remembered that there is nothing gained in superficial statistical accuracy at the expense of basic information.

Offices of vital statistics should refrain from questioning diagnoses made along approved clinical lines, unless there is some reason to doubt their validity. The ultimate classification of causes of death should not be left to laymen but should be made by professionally trained individuals.

With regard to the classification of deaths reported along etiologic lines, it is suggested that they be placed in subtitles under their various respective causative factors. This can be accomplished without materially affecting the present scheme of recording vital statistics. There is a precedent for this in the case of congenital cardiac malformations. These are not tabulated as heart disease but in a separate subtitle under congenital malformations. Similarly, deaths reported as thyrotoxic heart disease should be placed in a separate category under exophthalmic goiter or toxic adenoma of the thyroid. Those from syphilitic heart disease and aneurysms of the thoracic vessels due to syphilis should be tabulated as definite subtitles under syphilis. Although, strictly speaking, in view of the recent work by Rothschild, Kugel and Gross,¹² who have found

evidence of active rheumatic infection in most cases of rheumatic heart disease, all deaths from rheumatic heart disease should be placed under rheumatic fever, it is doubtful whether this can be done at present without too greatly disrupting the prevailing scheme of recording vital statistics. It is recommended, however, that deaths so reported be set aside in separate categories under heart disease. Similarly deaths from hypertensive and arteriosclerotic forms of heart disease should be listed as distinct entities.

SUMMARY AND CONCLUSIONS

1 The present method of reporting and tabulating heart disease mortality statistics does not reflect a true picture of heart disease mortality. Only 80 per cent of deaths occurring in hospitals in a large city and tabulated for the purpose of vital statistics as due to heart disease were found on examination of the hospital records to be due to that cause, while only 62 per cent of deaths due to heart disease were so officially recorded. It is not possible to obtain an accurate conception of the total number of deaths from heart disease or of any of the various etiologic types.

2 Within certain limits, the more accurately heart disease is diagnosed the less reliable are the official mortality statistics. This is due to the difficulties in interpreting diagnoses made along etiologic lines in terms of the International List of Causes of Death. It is quite likely that with further advances in clinical medicine these points of view will become more divergent and vital statistics even more unreliable.

3 Steps should be taken to remedy this situation. It is proposed that heart disease when reported along etiologic lines shall be tabulated as subtitles under the respective etiologic categories. Consideration should be given toward eventually revising the International List of Causes of Death so that heart disease mortality may be officially recorded on an etiologic basis.

4 Physicians are urged to use etiologic diagnoses in reporting heart disease mortality. Registrars of vital statistics should be most loath in questioning death certificates containing approved clinical terms.

5 It should be recognized by practicing physicians, coroners and statistical officials that the employment of superficially accurate diagnosis based on insufficient evidence results only in the vitiation of mortality statistics in general.

6 Many diagnoses of heart disease are made without sufficient evidence. While the use of an etiologic terminology is not suggested as a panacea for intentional misstatements, it is believed that fewer mistakes are made when heart disease is diagnosed in terms of its causative factors.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS SPRAGUE AND WHITE, COHN, FAHR,
STROUD AND HEDLEY

DR. HAVEN EMERSON, New York. The International List of Causes of Death undergoes a decennial revision at the beginning of each decade, at which time organized clinical and pathologic opinion has opportunity to effect desirable changes in terminology. Preliminary recommendations for the revision that will be made in 1938 have already taken into consideration suggestions for classification of deaths from heart diseases offered by a committee of clinicians of the American Heart Association. Etiologic classification is used whenever practicable throughout the list. Until recently, following such papers as those presented by Dr. Fahr, there has been no

¹¹ Manual of Joint Causes of Death. U. S. Department of Commerce, Bureau of the Census, 1932.

¹² Rothschild, M. A., Kugel, M. A. and Gross, Louis. Incidence and Significance of Active Infection in Cases of Rheumatic Cardiovascular Disease During the Various Age Periods. *Am. Heart J.* 9: 586 (June) 1934.

approximate agreement as to the specific etiology of the 80 per cent of all deaths attributed to heart diseases, apparently chiefly related to the process of senescence. The registrar of vital statistics of the local or state health department has recourse to the querying of death certificates by mail. When ambiguity of terms occurs there is uncertainty as to relative importance of primary and secondary causes as stated by the physician. This is not to be considered a criticism of the clinician who certified to the cause of death but as a means of avoiding errors in classification. The registrar cannot practically follow the method used by Dr Hedley, and I doubt whether the method can be relied on to improve the accuracy of death certificates. In general the cause of death certified by a physician who cared for the patient during life and observed the manner of death is a more valuable record than the opinion of a subsequent student of the record who did not see the patient dead or alive. It is important to recognize that such standard lists as the International List of Causes of Death and the National Standard Nomenclature of Disease represent only an approximation to an ideal and lag somewhat behind the ideas of specialists. They are, however, indispensable for comparability of morbidity and mortality experience and are responsible for a high degree of trustworthiness in American vital statistics and for the records of disease prevalence in the leading hospitals in this country. I assume that Dr Sprague distinguishes in his own mind between decrease in heart disease attributed to syphilis and decrease in the incidence of syphilis itself. No one can have heard the statements and seen the charts offered by Dr Cohn without being impressed by the necessity of withholding all judgment on trends in cardiac mortality unless age specific death rates for each of the rubrics of heart disease are presented. In a general way a good index of a high level of health of a community is found in a low and decreasing death rate from heart diseases in persons less than 50 years of age and a high increasing rate in persons 60 years of age and over. Improved life expectancy at all ages up to 60 years and lowered mortality from practically all preventable causes of death are consistent with a rising death rate from heart diseases, particularly in persons over 60 years of age.

DR HAROLD E. B. PARDEE, New York. Dr Sprague's summary of our present knowledge of the prevention of the different etiologic types of heart disease shows us just where we are strong and where we are weak. When it comes to hypertension and arteriosclerosis, we are barren of definite suggestions because we do not properly understand the cause of these conditions. It is important to reveal the relative weight of coronary arteriosclerosis and hypertension in producing the cardiac syndrome of failure. Only with this in mind can one clearly understand the role of hypertension. I feel that hypertension has been overstressed by many and I would be inclined to give arteriosclerosis more importance in these patients than it has often received. I do not intend to imply that it should have more importance than Dr Fahr has given it. Dr Stroud's work is along practical lines, because after all, physicians have more to do with the management and treatment of patients with heart disease than they do with prevention. Since patients have heart disease and must work during so many years when they have heart disease and since heart disease is being discovered so much more frequently in its early stages by the industrial, life insurance and school examinations, a practical study along these lines is important. The factors to be taken into account in considering occupation are multiple. We must be concerned with the influence of the patient's projected occupation on the etiologic factor of his disease and with its influence on his functional cardiac capacity. Lastly there are occasional anatomic features which must be taken into consideration such as the influence of a large aortic dilatation due to syphilis or arteriosclerosis. Dr Cohn's work has impressed me with the importance of using thought rather than mathematical processes in the analysis of figures. Such an analysis is vastly more important than the mere tabulation that is usually presented to the medical profession and that has led, as he pointed out, to various errors. Of course, the influence of changing diagnostic titles during past years is a difficult one to eliminate. It certainly has been present and

there, of course, one encounters the difficulties suggested by Dr Hedley. Certainly with the large percentage of autopsies which Dr Hedley has obtained, his results must be nearly enough correct to have demonstrated an error of enough magnitude to be important. What influence this will have on the mortality trend I cannot say. I am in accord with his suggestions for changes in the nomenclature of heart diseases. I feel that they should be allocated to the particular etiologic factor and that one should say "heart disease due to rheumatism" or "heart disease due to syphilis." There should be subheadings under the etiologic factor in each case. With this sort of diagnosis the knowledge of the frequency of the different types of heart disease would be definitely available.

DR TIMOTHY LEARY, Boston. From the data collected the evidence that cholesterol is the cause of atherosclerosis is as definite as the evidence that the pneumococcus is the cause of lobar pneumonia. The average physician pictures arteriosclerosis from his memory of the aortic lesions. These lesions are so varied that a single agent would not be expected to cause them all. However, studies demonstrate that the diverse character of the lesions depends on more or less distinct reactions to cholesterol at different age periods. In the aortic lesions of the young, phagocytic cells pick up imbibed cholesterol esters in the aortic intima modify them as the cells become amebic, split the lipid into finer and finer droplets and cause it to disappear. This definite metabolism of cholesterol within lipid cells is associated with a stimulation of the subintimal connective tissue. The growth of this tissue is limited, and with the rapid removal of the lipid minimal scarring results. In the middle period of life this metabolism of the lipid is slowed. The new connective tissue ages, secretes collagen and becomes scar tissue, so that scarring is the characteristic picture in this period. In the late period of life, cholesterol metabolism ceases and the lipid cells tend to pile up without adequate supporting tissue and undergo nutritional necrosis with the formation of atheromatous "abscesses," which are typical of this period. The evidence that cholesterol is the cause of atherosclerosis is based not only on the studies of human lesions but on the experimental reproduction of the disease in rabbits. It is further supported by the results of unintentional human experimentation in the treatment of diabetes. During the decade 1920-1930 high fat diets, rich in substances containing cholesterol e. g., butter, cream and eggs, were used in the treatment of diabetes. Shields Warren drew attention to the tremendous increase of arteriosclerosis in diabetic patients so treated. There was not only an increase in the disease in adults but x-ray shadows of calcified leg arteries were obtained in children as young as 4 years of age. During the more recent period, under low fats in diabetic diets adult arteriosclerosis has diminished, and roentgen evidence of the disease in children is no longer obtainable. Heredity and race may play a part in the etiology, stresses are important and the influence of endocrine factors may play a part, but inadequate cholesterol metabolism is the principal cause.

DR S. ADOLPHUS KNOPP, New York. There have been many statistics as to the number of cardiac diseases and their treatment. I think, however, that too little attention has been paid to the prevention of heart disease and arteriosclerosis. More physicians fall victim to angina pectoris than any other group of men. Perhaps it is due to overwork and an irregular life in general, and all one can say in warning is that self preservation is as important as the care of others. For the prevention of attacks of angina pectoris and congestive heart conditions in general, total or partial thyroidectomy has been performed. This operation is considered dangerous by many. The ligation of both superior and inferior thyroid arteries has been resorted to with varying results. The latest in cardiac surgery is Lyon and Horgan's method, consisting in the "dissociation of the thyroid from the sympathetic nervous system and the reduction of the blood supply to the thyroid." I have no new medical measures for congestive heart disease and arteriosclerosis. Diaphragmatic respiration has been helpful in preventing attacks of angina pectoris, and if in addition the patient learns what he can or cannot do, he has a good chance of prolonging his life. Controlled diaphragmatic respiration is not only helpful in early tuberculosis, as it gives relative rest to the upper lobe usually the first invaded, but is also beneficial

in arteriosclerosis, because it increases the oxygen supply and massages the heart and the aorta, thus preventing the thickening of the intima of the coronary arteries

DR SAMUEL FRIEDMAN, New York. Though the causes of arteriosclerosis are not definitely known, a larger proportion of people after 40 suffer from angina pectoris and high blood pressure than formerly. Neither the medical profession nor the government has yet planned anything definite for this great mass of sufferers, from whom I believe as much good could be accomplished as in typhoid and tuberculosis. Some people have low blood pressure and others have high blood pressure. In 1920 I reviewed the statistics of the health departments of New York, Philadelphia, Chicago and Cincinnati and found that the mortality rate from these diseases had increased about 100 per cent from 1900 to 1920. I felt that perhaps the two hours unwholesome travel to and from work daily, under the prevailing overcrowded conditions, added considerably to the wear and tear of the cardiovascular system. It occurred to me that a national five day (work) week would mend that damage by giving the people a two day rest. A word as to the prevailing abuses in the school and traction systems. Children who have just recovered from serious febrile diseases must on their return to school walk the stairs in line with the healthy ones several times a day during change of periods. This unquestionably may hurt many whose myocardium might still be affected though showing no murmurs. Those children should either use the elevator or be allowed to come a few minutes later to classes for about a month. The overcrowding of subway trains and climbing of subway stairs inevitably inflict serious damage on senile and diseased hearts. Many of these patients not only become winded but get attacks of angina. Occasionally one succumbs on reaching the street, having been pushed upward along the stairs. To overcome these two abuses, my idea would be that persons with active or potential heart disease should receive a medical certificate entitling them to a seat during the rush hours in a car designed for that purpose. Also, any subway lower than 20 feet should be provided with an escalator.

DR HAROLD B WOOD, Harrisburg Pa. Some of the inaccuracies in our heart statistics are due to the physicians themselves not understanding how to fill out death certificates, wrongfully omitting important causative conditions or improperly inserting extraneous diseases or incidental operations. Those of us who have the opportunity of instructing students or physicians in any way as to the proper method of recording causes of death should use this opportunity. If a physician writes "chronic heart disease" on the death certificate, with a ruptured gallbladder, acute alcoholism, influenza, bronchopneumonia or a cerebral hemorrhage, which are obvious causes of death, the cases become classified as deaths from heart disease thereby giving incorrect death rates from heart disease. Physicians who write articles on heart disease and compare statistics of the present time with those of ten or twenty years back do not realize that the records are not at all comparable. During these years different systems of recording, coding and tabulating deaths have been adopted. Those who write to different cities for their records on any disease whatever, to compare one city with another, do not realize that the records are not comparable. Until recently Philadelphia, New York and Chicago used absolutely different methods of tabulating their causes of death by using different systems of coding when two or more causes were recorded on the death certificates. The action of federal and state authorities making inquiries of physicians for better information on death certificates was brought out in the last paper. Thousands of certificates are incomplete. The queries sent out obtain many corrections and better records. Thousands of death certificates are signed by practitioners of various sects and by other laymen. Should they be tabulated and accepted with the causes of death as determined by physicians? A few years ago the matter was brought up of the importance of tabulating only death certificates signed by physicians, but that system has not been put into practice as yet as it should. These few points illustrate the absolute absurdity of using decimals in death rates.

DR HOWARD B SPRAGUE, Boston. I am glad that Dr Emerson brought out the fact that there was a decrease in some of the tertiary manifestations in our part of the country

and not necessarily in the infection itself. In this connection it is of interest to remember that it is now just twenty-five years since the original discovery of the arsenicals for the treatment of syphilis, and that is about the average time for the development of cardiovascular syphilis after the primary injection. It may be that we are at the beginning of a period of great decrease in these late manifestations of syphilis, as the result of improved methods of treatment.

DR GEORGE E FAHR, Minneapolis. Dr Pardee put his finger on the crux of the situation in hypertensive heart disease. It is the evaluation of the two factors of increased work for the left ventricle and the decreased oxygen supply to the left ventricle consequent on the coronary arteriosclerosis. I don't think that one can say at this time which is the more important, but from an extended study of this subject I would say that it varies from case to case. In a man or a woman with a very high blood pressure and a very moderate amount of coronary arteriosclerosis the important factor in heart failure will be the hypertension, and there are patients who have had a high blood pressure for many years. The roentgenogram first of all shows evidence through the dilatation of the left ventricle that there has been a hyperdynamic condition produced in the left ventricle musculature, consequent to the hypertension, and at autopsy in a few cases no arteriosclerosis of the coronaries is found. On the other hand there are cases with moderately low blood pressure and a considerable degree of coronary narrowing and the most important factor is the coronary narrowing with the consequent ischemia of the heart muscle, so I think that the two factors cannot be separated. They work to produce ultimately a heart failure in hypertension provided a patient doesn't die of uremia, cerebral accident or something else before that. Certainly when hypertension works alone the patients live on the average from ten to fourteen years before mild symptoms of dyspnea are produced in hypertension when there is no coronary disease present, and then they live longer because of careful handling of the case after the first symptoms, even after the first severe congestive failure, and then die of uremia, septicemia, apoplexy and so on. In one case the hypertension is the most important factor, in another the coronary arteriosclerosis.

DR O F HEDLEY, Philadelphia. Dr Emerson apparently misunderstood several of my statements. He stated that of 450 deaths considered due to heart disease 416 of them actually were, making a very small balance. Dr Pardee in his discussion restated the matter correctly. Seventy-one, or 20 per cent, of 350 deaths reported as heart disease were found to be due to other conditions while among 450 deaths due to heart disease only 279 or 62 per cent, were so recorded. These figures speak for themselves. The nomenclature sponsored by the American Heart Association is the best one at present. It or some other form of etiologic nomenclature is being widely used in clinics and hospitals throughout the United States. The etiologic diagnosis of heart disease is a fact and not a theory and must be reckoned with in computing vital statistics. While the Public Health Service has not seen fit to adopt the Standard Nomenclature of Disease for use in the marine hospitals it is in the process of adopting an etiologic nomenclature. The recording of vital statistics is not a function of the Public Health Service. Dr Pardee spoke of the desirability of having all rheumatic heart diseases grouped under rheumatic fever, the ultimate etiologic factor. I thoroughly agree with him but doubt whether it can be done without too greatly disturbing the International List of Causes of Death. It may be necessary to work out a plan by which heart disease can be tabulated and reported along etiologic lines and still conform to the International List. This could be used either in the United States as a whole or in cities or states as desired. Dr Wood mentioned the desirability for improvement in death certificates. More time in medical schools should be devoted to teaching prospective physicians the correct method of certifying the causes of death. This should be included in the courses of preventive medicine. The average undergraduate course in preventive medicine devotes too much time to the mechanics of public health. This is an era of specialization, and about 95 per cent of physicians never encounter such problems in after years. All of them, however, sign death certificates.

THE CONTROL OF MYOPIA

EDWARD JACKSON, M.D.

DENVER

A paper read before this section in 1891 stated that¹ "the constant wearing of full correction lenses, no matter what their strength, with careful attention to other points of ocular hygiene, checks promptly and permanently the advance of myopia in the majority of cases." In 1892 in a paper on the full correction of myopia, read before the American Ophthalmological Society, I² asserted that "myopia should be fully corrected and the correcting lenses constantly worn, except at such times and to such extent as the emmetropic eye would require the aid of convex lenses for presbyopia." Supporting this, twenty-seven cases were reported that had been under observation three years or upward with this treatment. At the same meeting Dr. George C. Harlan³ reported thirteen cases of high myopia, from 4 diopters upward, in which full correction had been worn constantly for more than five years, and stated that "excessive convergence without accommodation is the most important factor in progressive myopia."

Before that time Foerster⁴ had published his observation that constant wearing of glasses, fully correcting, or overcorrecting the myopia, did not lead to increase of myopia, which he supported by the histories of fifty cases. Many observers had reported statistical studies of the eyes of infants and school children proving that myopia was very rarely present at birth but arose and was progressive during school life. These statistics for children were brought together and correlated by B. Alexander Randall in two papers, published in 1885⁵ and 1890,⁶ and W. F. Norris⁷ had stated that, in more than forty new-born children examined with the use of atropine, all the eyes were hyperopic.

The significance of the facts so accumulated was lost, however, in the attention given to theoretical explanations of myopia, although all admitted the truth of Donders' statement that "a myopic eye is a diseased eye." It was generally admitted that the refraction increased in the eyes of children, hyperopia grew less and myopia increased, but theoretical explanations claimed more attention than clinical facts. It was thought of as a step in evolution, when the theories of Darwin were poorly understood. It was attributed to some congenital defects, such as softness of the scleral tissues. Peculiar shapes of head and orbits, anomalous positions of attachment of the ocular muscles were suggested. With more reason astigmatism, newly discovered, was blamed for causing myopia.

The view of progressive myopia put forward by Dr. Harlan is still not understood by ophthalmologists. N. Bishop Harman of London, who has worked for thirty years for the establishment of myopia schools and sight-saving classes, is puzzled. He says "It is very difficult to control the progress of even low degrees of myopia in some school children." He also suggests "Stop all schooling and reading for at least a year, let the child run wild, preferably at the seaside." The

whole subject of myopia needs to be considered in the light of actual experience of the results obtained by applying such suggestions to the prevention and limitation of myopia.

To this end 381 cases of myopia (755 eyes) seen in private practice, determined with cycloplegia and followed through periods of from two to thirty-nine years, an average of nine and one-half years, have been studied and tabulated. They include patients of all ages, from 4 to 82 years, and have been grouped and studied according to the age periods at which they came under observation and at which the constant wearing of the full correction was begun. Other ophthalmologists who have case records with good data can make similar studies of their own experience. When the eye begins to be myopic it is a diseased eye, and the results of such changes in it lead to grave disability and blindness in an important proportion of cases. The careful study of myopia is a step toward the prevention of the blindness of later life. It is not yet known to what extent blindness from cataract and retinal separation depend on myopia or how, through the general nutrition of the eyes, myopia and glaucoma may be related or opposed to each other.

Percentages in Age Groups

| Age | Myopia Changes | | | | Vision Changes | | | |
|----------|----------------|------|----------|-----------------------|-----------------------|----------|------|----------|
| | Increase | None | Decrease | No Change or Decrease | No Change or Increase | Increase | None | Decrease |
| Under 10 | 69 | 16 | 2 | 41% | 89% | 58 | 37 | 5 |
| 10 to 20 | 42 | 47 | 11 | 58% | 91% | 61 | 30 | 9 |
| 20 to 30 | 19 | 58 | 23 | 81% | 93% | 42 | 51 | 7 |
| 30 to 40 | 24 | 53 | 23 | 70% | 87% | 52 | 35 | 13 |
| 40 to 50 | 20 | 60 | 20 | 80% | 75% | 40 | 35 | 25 |
| 50 to 60 | 16 | 60 | 24 | 84% | 76% | 21 | 54 | 25 |
| Over 60 | 23 | 45 | 32 | 77% | 42% | 14 | 23 | 58 |

The accompanying table shows that under 10 years of age the tendency toward myopia is general and that in most myopic eyes the defect is increasing. When one bears in mind the fact that at birth practically all eyes are hyperopic, it is safe to say that in all young children there is a tendency toward myopia. After the age of 20 this tendency has disappeared and the majority of myopic eyes show little or no increase. In later life, after 50, there is a tendency to decrease of myopia, although the cases of senile myopia, so-called second sight, balance the physiologic lessened hyperopia of childhood.

When case records are studied individually there appears to be strong reason for accepting the classification of anterior and posterior myopia that was adopted by Risley. The anterior myopias are the cases that have been classed as conical cornea, and slight dislocations and deformities of the lens. Anterior myopias are associated with high degrees of astigmatism. Two of these patients, followed from 7 to 15 and from 10 to 17 years of age, had bilateral, partial dislocation of the lens, and the myopia increased, although the high astigmatism did not increase. Nearly all the high anterior myopias appearing later in life, in patients from 16 to 48 years of age, were cases of corneal change, keratoconus.

Decreases in myopia did not occur before 10 years of age, but in some patients, placed that early on constant use of the full correction, decreases appeared before 20. From that time on, about one case of myopia in five showed increase until over 60, and after that about

one in three. Such decrease in the amount of myopia corresponds with the increase of hyperopia, found by Priestley Smith in his studies of the growth of the crystalline lens, between 25 and 65 years of age.

The increase of vision shown, not the better vision with correcting glasses but vision developing gradually as the glasses were constantly worn, was a matter of surprise. It began at the earliest age, and was found at all periods of life. In early life it might be ascribed to the gradual gain in visual acuity, commonly seen after the correction of astigmatism in young people. But after 30 it was best explained by the general improvement of the nutrition of the eye, with the wearing constantly of glasses that placed it on a footing of equality with the emmetropic eye or with the hyperopic eye not used excessively for near work.

The rather steady proportion, at all ages, of eyes that showed no change of visual acuity, as well as of those that showed no change of myopia, supports the idea of improved ocular nutrition under the conditions of using the eyes with the advantage of full corrections. The small proportion of eyes in which vision decreased, not more than one in four, even after middle life, should dispel the idea that nothing can be done to control myopia and preserve the usefulness of myopic eyes. Myopia can be controlled by removing its causes and securing the essential conditions for healthy eye work.

CAUSES OF MYOPIA

What are the causes of myopia? Certain congenital tendencies act under conditions unfavorable to ocular health. Under the influence of the work of Donders on the accommodation and refraction of the eye, the ophthalmologists of seventy years ago thought first of accommodation and astigmatism. Donders feared that accommodation had an important influence in causing myopia. Landolt based his rules for the care of myopia on that supposition. Graefe had pointed out that, when a young person with pulsating retinal veins fixed and focused vision on a near object, increased pulsation showed increased intra-ocular pressure. He arrived at the conclusion that the increased pressure was due to the accommodation of the eye.

Repetition of Graefe's experiment with the eye under observation with the ophthalmoscope subjected to complete cycloplegia by atropine, shows that the increased pulsation is not caused by accommodation but by convergence. Years ago the experiment was tried on an eye with oculomotor paralysis—complete ophthalmoplegia externa, but with good accommodation. The distinct venous pulse was not increased by the maximum exertion of the accommodation. There was not the slightest increase of the pulsation. It was only in later years that full understanding of the cause and mechanism of myopia was arrived at. Harlan was right. His view that myopia depends on excess of convergence has been confirmed. Decrease of convergence, even by wearing full correcting glasses, with increase of accommodation, controls myopia. And the same result may be secured by the use of prisms base in to diminish convergence.

ANTERIOR MYOPIA

Anterior myopia is caused by distention of the globe at the anterior pole. The center of the normal cornea is thinnest, the periphery has greater thickness, and the central and peripheral zones differ somewhat in structure.⁸ The normal balance between the intra-ocular

pressure and the sclerocorneal coat of the eye is usually maintained with great exactness. But sometimes, after general illness affecting tissue nutrition, the cornea gives way before the intra-ocular pressure, producing keratoconus and increasing the anteroposterior length of the eyeball. This process is checked by absolute avoidance of near work for the eyes, with complete correction of the myopia and astigmatism already present, and measures to restore normal metabolism. This should be conscientiously planned and persistently carried out, before any operative measure to change the shape of the cornea is considered.

POSTERIOR MYOPIA

Posterior myopia is what is commonly meant by "myopia." It includes "progressive myopia," "malignant myopia" and other groups of cases that are given special names. It has long been the subject for theories and academic discussions. Its causes, complications and sequels give it a major place in ophthalmic literature. But the distention that causes it does not begin, or center, at the posterior pole of the eye. Its pathologic changes begin, continue and are most extensive at the temporal side of the optic nerve entrance.

There are very few cases that do not show their chief lesions in this situation. The descriptions and illustrations of cases, and the sections of myopic eyeballs, all emphasize the fact. The myopic crescents, the myopic atrophies, have this location. The choroidal "halo atrophy" due to increased pressure of chronic glaucoma is entirely different in appearance and distribution. It appears equally advanced and equally broad all around the optic nerve entrance, with usually no pigment changes. The characteristic appearances of the myopic fundus are shown in all the atlases of ophthalmoscopy. Even where the picture is not intended to represent the fundus of a myopic eye, the crescent of myopia is sometimes noticeable. This illustrates that fundus changes may be started in eyes becoming less hyperopic, which do not go on to myopia.

CONVERGENCE

In most mammals the eyes are placed laterally, so that the two cannot be fixed on the same point. Binocular fixation, binocular vision, appears only in some of the cat tribe and in the primates. In the human embryo the primary optic vesicles start on opposite sides of the head but in the development of the eye are pushed around to the front, with the visual axes about parallel. In the human infant binocular vision is rudimentary at birth and is developing up to the sixth year, or later. The infant, looking at objects held in the hand close to the eyes, develops both binocular coordination and accommodation and probably diminishes the hyperopia that practically all eyes have at birth. The exercise of these new functions is quite intermittent. The infant looks at its hand and then away at something else—the typical exercise for growth.

Going to school, with set tasks requiring continued near looking, has a very different effect, physiologic hyperemia becomes pathologic. The educational process becomes dangerous in direct proportion to its scholastic efficiency. Risley⁹ described the lesion produced as a "limited choroiditis of varying extent and intensity, affecting the region of the nerve entrance and generally manifested at the temporal margin of the optic disk as a crescent of altered color and pigment absorption." Norris⁷ reported eleven cases and Risley seventeen

such cases that were watched for years, passing "from the hyperopic eyeball over into near sight, through the turnstile of astigmatism" Risley strongly emphasized the effect of astigmatism in producing such changes. Other factors are corneal opacities, poor lighting, a stooping posture and impaired general health, on which Batten¹⁰ inclined to put all the blame for myopia. Perhaps the work of Norris and Risley failed to produce the impression it should, because they did not point out the enormous importance of the mechanical effects of excessive convergence.

Any one who turns in its socket the eye of a patient rendered unconscious and relaxed by general anesthesia will realize that the main obstacle to free movement of the eyeball is the rigid optic nerve, firmly attached to the sclera. This, much more than the check ligaments or the tonus of the extra-ocular muscles, limits the free movements of the eyeball. In convergence this resistance is constantly added to that of opposing muscles and other tissues. The forces meet all around the attachment of the optic nerve and its sheaths to the globe, around the optic nerve entrance. But the effects produced on the nasal and temporal sides are quite different. On the nasal side the tissues are jammed together by the turning in of the eyeball. On the temporal side the tissues are put on the stretch, and the choroid, with its vascular nutritive tissue, is pressed between the firm sclera and the outward pressure of the contents of the eyeball. These mechanical factors are quite sufficient to account for the pathologic changes in this region revealed by the ophthalmoscope and in the eyeball examined by the microscope after removal.¹¹ These changes are produced directly by excessive and too long continued convergence. They are not merely a symptom, they are the constant and essential lesion of myopia. They may be prevented by stopping and avoiding excessive convergence.

This has now been proved by sufficient clinical experience. Other theoretical explanations of myopia can be set aside until excessive convergence has been eliminated. Its elimination by constant use of correcting lenses and attention to posture puts the myopic patient on the direct road to safety. As myopia becomes high, above 6 diopters, the overstrain of convergence causes exophoria, which goes on toward divergent squint. This may require the assistance of prisms base in, or it may go on to divergent squint, and stopping convergence usually checks what has previously been a progressive myopia. The statistics recently published by Marlow¹² illustrate this.

This study of the effects of full correction shows that even for bad cases of progressive myopia the prognosis is not hopeless. The weakening, atrophic process does not extend forward to the anterior segment of the sclera. The illustration, which Sir John Parsons¹³ credits to Heine, representing a section of the normal eye laid on a section of a highly myopic eye shows this. The anterior sclera reinforced by the insertions of the rectus muscles, their connecting bands, the ciliary ring, the doubled capsule of Tenon, seem never to suffer from the stretching, thinning process of high myopia, although the anterior sclera does give way, in rupture, or staphyloma, in other pathologic conditions. The same is true of the temporal part of the posterior

sclera, which is supported by the tendons of insertion of the oblique muscles and the bands of scleral tissue that receive their stress. The unknown "tendency to scleral softening," which has been assumed to be the basis of scleral distention, is narrowed down to the region to the temporal side of the optic nerve entrance, especially subject to convergent stress.

The more remote pathologic sequels that have been associated with myopia, cataract and detachment of the retina are not necessarily results of myopia, and probably ignorance of the pathologic relation between them and myopia exaggerates its importance. Cataract is sometimes associated with other forms of choroidal disease, and its association with myopia may have no peculiar significance. The recent evidence of shrinking and detachment of the vitreous, before detachment of the retina, which has been emphasized by Lindner, may be a more direct result of the pathologic sequence of myopia. But in any case the indefinite danger of such sequels is a sound reason for stopping the development of myopia in its early stages. The dangers may have been exaggerated, but they exist. The teaching of toleration and indifference toward beginning low myopia needs to be sharply reversed. The evidence of the tendency to myopia and its beginnings should be sought at the start of school life, and the check of full correction by lenses and posture, the breaking up of habits of excessive convergence, is one of the most important applications of school hygiene.

Myopia is not a subject for theoretical speculation and hypotheses, it is a possible danger to be met, prevented, and eliminated from the life of the growing child. Its cause was long a mystery. The suggestion of the mathematician Kepler that near seeing caused myopia was buried under two centuries of speculation and academic discussion. The authority of Graefe directed attention away from convergence to accommodation. Pathologists searching with compound microscopes could not recognize a mechanical factor in causation. Cohn's statistics showed myopia increasing from 14 per cent in the lowest school grades to 59.5 per cent in the theological graduate school of the university. Risley found that the proportion mounted year by year in the schools of Philadelphia, and Derby, using atropine, proved that it increased from 35 to 47 per cent of the class in four years at Amherst College. These are now confirmed by extended clinical experience. The matter is worthy of attention.

Republic Building

ABSTRACT OF DISCUSSION

DR. ALBERT C. SNELL, Rochester, N. Y. Since myopia is very common, it is natural that some ophthalmologists question the efficacy of any or of all modern efforts to control it. Dr. Jackson's present dictum that 'myopia can be controlled by removing its causes and securing the essential conditions for healthy eye work' is encouraging. From the statistics which I have studied the general deduction is made that the number of myopic cases in public schools today is not diminishing but that the degree of myopia in the present school generation is much less than that of previous decades. Dr. Jackson's paper presents several surprises. The first is his deduction that after the age of 20 one patient in five showed a decrease in myopia, and the second is the large percentage of myopia patients showing an improvement in visual acuity. In a review of 1100 cases of myopia I found that only 2 per cent showed a decrease in myopia up to 30 years of age, and 4 per cent showed a decrease after 30. My studies of myopia do not reveal the large percentage of cases with improvement in visual acuity shown in Dr. Jackson's table.

13 Parsons I H Pathology of the Eye New York, Putnam's Sons vol 3 p 915

In the same records considered previously I found about 6 per cent with improvement in visual acuity, in contrast with the 40 to 61 per cent shown in Dr Jackson's table. About 50 per cent of myopia seems to be developmental, self limited and but little influenced by the use or nonuse of glasses. In this class the myopia is of low degree and becomes stationary before the age of 25. In contrast with this class and at the other extreme are found the progressive or malignant myopias. With regard to the latter and the intermediate class of myopias, I agree with Dr Jackson that the combination of the constant use of full correcting lenses, restriction of visual tasks and attention to proper general and ocular hygiene has produced favorable results in their control.

DR F T TOOLE, Montreal. Control is the holding in check of a pathologic process or possibly the elimination of elements that may predispose toward the creation of causative factors. One speaks of the control of tuberculosis, scurvy and rickets through adopting ways of living which prevent their genesis. Is it not equally true of myopia that its control consists in adopting rules of life that inhibit the creating of the prodromal causative factors? In myopia one is not merely dealing with a refractive error. Donders has truly said that every myopic eye is a diseased eye and that such an eye is as much a cripple actually as the lesion in a hip joint. Both can be controlled but both might have been prevented. Relatively low errors of myopia may be associated with retinal detachments, lens changes, vitreous opacities and a host of other pathologic changes that hold up progressive myopia as one of the commoner contributing factors in the loss of sight. The healthy offspring of a myopic parent is prone to inherit myopia much more so than the child of hypermetropic parents and the greater the degree of myopia in the parent the greater the likelihood. No one can challenge that heredity is a predisposing factor. I have only to refer to such authorities as Pflüger, Schneller and Tschering. With the new-born child introduced into the world without an actual physical handicap other than a predisposition should not our debt to society compel us to adopt more rational methods for the education and upbringing of our children? One has only to regard the figures taken from the upper grades in school statistics to note the inroads that have been made by myopia. So many children often defective physically and handicapped by a fore-ordained heredity, should not be encouraged in the intensive application of near vision. Are there not too many highly educated people today and would not many do better if they were told at the outset that a life demanding close application was unsuitable for them? One cannot transfer all one's myopia subjects to the mid-Atlantic where convergence is reduced to a minimum but there is a happy medium. The establishment of sight saving classes is a step in the right direction but a great deal of instruction can be given by the ear rather than by the eye. The facility of using artificial light at all hours of the day and night encourages a precocious child to indulge in perverted practices that ultimately assume a psychology almost pathologic in character in its unwillingness to indulge in moderation or restraint.

DR S W NEWMAYER, Philadelphia. In a recent survey a CWA project in Philadelphia, 16,200 high school boys and girls were studied for their eye status. An amount of myopia sufficient to reduce vision to 15/50 or less was found in 425 boys and girls. Of these, twenty-seven had more than 6 diopters of myopia and 398 had less than 6 diopters. In the sight saving classes of Philadelphia 190 pupils are enrolled, sixty-seven have been placed because they possess excessive myopia, but only three of these have a vision of 20/100 or less. Cases of myopia in sight-saving classes show little or no progression and rarely any decrease in vision. This I believe is due in part to maintaining a full correction of the defect.

DR MEYER WIENER, St. Louis. I think that certain statements made by Dr Jackson which he states as facts should not go unchallenged. He states that fifty years or more ago authors proved that myopia was produced by the use of the eyes for close work. I admit that many authors fifty years ago did maintain and many down to the present time have

maintained that such is the case. I do not admit that this has been proved. Dr Jackson also states that myopia is produced by excessive convergence. I take exception to that statement. I don't think it is proved. I think that there are many things which can controvert that opinion. In the first place it is taken for granted that, because myopia increases during the grammar and high school age, it is the use of the eyes for close work that produces or increases it. The fact must not be lost sight of that this is the period of greatest growth and that during this period, whether the eyes are used for close work or not, if there is a tendency for the production of myopia or the increase of myopia it will occur whether the children are going to school or are not using their eyes at all. There is one thing that to my mind is unanswerable. Why is it that if the use of the eyes for close work in school is the cause of myopia after one reaches the university it ceases to increase and it doesn't increase? It increases to the greatest extent during the period of greatest growth, between the ages of about 9 or 10 and 17 and 18 or 19, and after that there is but little increase whether one uses the eyes or not. I think that statistics show this. Why is it that most domestic animals are myopic? They certainly are not using their eyes for close work and they certainly are not using the power of convergence. Wild animals are not myopic. If convergence produces myopia and produces it in the school age, why doesn't it continue to increase after the school period is finished? If convergence produces myopia why is it that persons with one eye can develop myopia? Why is it that persons who have no binocular single vision develop myopia and have myopia increase?

DR JOSEPH I PASCAL, New York. There is a type of myopia found in children which is of low amount and progresses slowly. It shows no pathologic fundus changes, and corrected vision is at all stages perfectly normal. This type of myopia seems to be due not to a stretching of the sclera but to a hypertonicity of the whole neuromuscular mechanism of the accommodation. It may be called for this reason tonic myopia. It is in a sense a permanent tonic spasm, though it can hardly be termed a true spasm. It is more nearly a state beyond the tonic spasm as the latter is a state beyond the clonic spasm. The cause of this type of myopia seems to be a primary exophoria. In these cases there is a fairly high degree of exophoria, more at distance a true divergence excess. The exophoria seems to be the primary condition and is due to a relatively higher tonicity of the divergence center. It is well established now that there is an active divergence center just as there is an active convergence center and that the balance of the eyes is determined by the relative tonicity of the two opposing centers. Exophoria, therefore, is not just a passive state resulting from over-relaxation of the convergence center but is an active state due to a relative overtonicity of the divergence center. Now this primary exophoria necessitates a continuously excessive convergence effort in order to obtain binocular fixation. And because of the association between the accommodation and convergence the excessive convergence tends to produce excessive accommodation resulting in a permanently hypertonic accommodative mechanism and resultant myopia. Not all children showing a primary exophoria develop myopia. The principal reason for this is that there is a variable intensity in the association of the two functions of accommodation and convergence. When the two functions are tightly bound the overactivity of the convergence will tend to produce tonic myopia. When the two functions are but loosely bound the desire to have clear as well as single vision will prevent the development of this type of myopia. A similar explanation though in the reverse direction, has been mentioned by Dr Maddox in explaining why some hyperopic children develop convergent strabismus and other hyperopic children do not. Considering the etiology of this type of myopia one method of control suggests itself. An effort must be made to dissociate the two functions of accommodation and convergence. By means of simple stereoscopic exercises, it is possible to loosen the bond between the accommodation and convergence. And this procedure seems indicated in this type of myopia in addition to other measures used in the case.

DR. WALTER B. LANCASTER, Boston The subject is obviously one of many sides and the solution is not simple, because myopia is due to a number of causes acting together. One man will emphasize one cause, and another will emphasize another. The causes may be grouped into two classes: the local causes in the eye and the causes that depend on hereditary and general hygienic health conditions. It is important to urge the parents and nurse to guide the habits of the child and to teach him the proper method of holding the book, especially of holding the book farther away. However, in a family in which myopia is hereditary one child grows up myopic, and then the next one comes along and he also develops myopia. So one wants something more to do. Many have tried Dr. Wiener's method of epinephrine. Some have tried Dr. Luedde's method of atropine in one eye. I am not sure whether he has published a report on that, but he has tried it for some years. It is based on the belief that convergence is to be combated. It seems to me that convergence is an important factor. What can be done to diminish it? Using atropine in one eye may in some cases suffice to favor suffusion and do away with binocular vision and allow the eye to diverge instead of converge, but if suppression with divergence is a good thing to produce, why not go a step further and use not only atropine in one eye but also cover it with the crinkly glass that is now available and so much less conspicuous than a ground glass or a black glass before one eye and yet effectively cuts down the vision? I have been using this method. It will take a long time to determine its value, so I am asking that some ophthalmologists try it. Perhaps five or ten years from now some one will have some more data.

DR. EDWARD JACKSON, Denver The discussion has shown that the problems of myopia may be approached from very different points of view. It is a large subject and it requires such studies as Dr. Snell has made and as Dr. Tooke has made and suggested and all the others. They will have to be brought together and coordinated before any general conception of the whole subject is possible. The matter of heredity has not been doubted at all. Immediately there arises in my mind a family in which the father and mother and the four children were myopic. This would probably have occurred even if they had been started to school with glasses or if glasses had been put on before they went to school. A former theory, which was frequently put forward before much was understood about the process of evolution, was that myopia was a preparation of the race for the use of the eyes for close work. I think that the statistics will show that perhaps 999 out of 1,000, or perhaps only 99 out of 100, are born hyperopic. The size of the eyeball, its length, the curves of the refracting surfaces all indicate that those eyes must be expected to be hyperopic and that they are more highly hyperopic than the eyes ordinarily encountered at school age. The vision of children certainly is not complete at birth or within a year or two afterward. But early they begin to be interested in objects that they can seize in the hands and bring as close as they please to the eye, in that way they get a large enough image to see, even if they do not have very good vision. Practically all children come to school age with the habit of looking at near objects too close to their eyes for complete accommodation and with more convergence than they ought to have after they get to working in school. Every year I see some children having trouble with their eyes who on examination are found simply to be holding the print too close to their eyes. The only way to meet this situation and control it is to test the child repeatedly with very fine figures by bringing the card closer and closer to the eye until the child begins to back off, that is, give it a lesson that it is easier for the eye to see things farther away. Then if the mother is taught that she must watch the child with reference to this, one will get rid of the excessive convergence of infancy. It is new to me that the domestic animals are found to be nearsighted. They have deficiency of vision and they lack the full foveal vision that human beings have. Generally the lower animals have hyperopia. They may occasionally have myopia. The statistics with reference to savage races show that they are nearly all hyperopic. I think that Dr. Randall's statement has never been controverted that hyperopia cannot be "healthfully outgrown." The myopic eye is diseased when it becomes myopic.

CHOLECYSTIC DISEASE

A COMPARISON OF THE CLINICAL WITH THE
CHOLECYSTOGRAPHIC DATA CONCERNING
500 PATIENTS NOT OPERATED ON

B. R. KIRKLIN, M.D.

AND

THOMAS W. BLAKE, M.D.

Fellow in Radiology, the Mayo Foundation
ROCHESTER, MINN.

The reliability of cholecystographic data when subjected to the test of operation and pathologic examination has been proved repeatedly. For example, of 4,676 patients examined by cholecystography in 1932 at the Mayo Clinic, 732 were operated on, and the cholecystographic report, whether positive or negative, was confirmed in 696 (95 per cent) of the cases. Among 287 patients whose cholecystograms were normal and who were operated on chiefly for diseases other than of the gallbladder, surgical exploration confirmed the cholecystographic diagnosis in 257 (89.5 per cent). Of 445 patients concerning whom cholecystographic data were positive, 439 (98.6 per cent) had disease of the biliary tract. Comparable statistics have been reported by many other roentgenologists, so that the trustworthiness of the method, so far as proof by operation goes, is well established and generally accepted.

Occasionally, however, the question as to patients not operated on is raised, the implication is that, as only those patients who give marked symptoms of disease of the biliary tract ordinarily are subjected to operation, the percentage of correct cholecystographic diagnoses may easily be high but that if all patients regardless of severity of symptoms were operated on, the record of cholecystography might be less brilliant. Those who raise the question are not disposed to doubt cholecystographic evidence of gallstones or tumors, even in the absence of symptoms, but intimate that in other instances cholecystography is perhaps merely a procedure of confirmation and not of independent diagnosis, that often the cholecystographic data are not in consonance with the clinical facts, and that mere impairment of function of the gallbladder, as shown by cholecystography, is not of itself significant of disease of the biliary tract.

With respect to such intimations, the concession must be made that cholecystography is primarily a test of function of the gallbladder at the time of examination and that it is a direct method of diagnosis only when gallstones, calcific deposits in the bile or in the walls of the gallbladder, tumors or deformities of the gallbladder are demonstrable. It will also be admitted frankly that the roentgenologist cannot determine absolutely whether impaired function alone, as indicated by absence or faintness of the dye shadow, is attributable to disease of the biliary tract, to disease of other organs directly or reflexly affecting the ability of the gallbladder to receive and concentrate dye, or to conditions unrelated to disease. Notwithstanding these considerations, since thousands of operations have proved that disordered function usually is a result of disease of the biliary tract, as a rule it is far safer to draw this inference than to assume that the cholecystographic indications of impaired function are probably attributable to other causes.

Session of the American Medical Association, Atlantic City, N. J., June
12, 1935.

Doubts as to the constant significance of cholecystographic indications of disordered function of the gallbladder may arise from lack of confidence that the technic of examination and the rationale of interpretation have been sufficiently perfected, or from a supposition that the normal gallbladder may be erratic in the performance of its functions, or from the hypothesis that its functions are often materially altered by diseases or abnormal states of other organs

Again and again, roentgenologists have emphasized the necessity of employing a scrupulous technic in administering the dye and in the roentgenographic procedure, regardless of the method employed, whether oral or intravenous. With either method the dose must be adequate, purgatives and other medicines that might interfere with the test must be interdicted, and food must not be taken by the patient except as ordered. For several years the relative merits of the two methods were in debate, but this has ceased since experience has shown that the oral method is just as dependable as the intravenous method if certain well known principles are respected. At the Mayo Clinic it is insisted that the dye be given in solution, which is required to be made palatable by the addition of grape juice and which is directed to be taken immediately after a full meal almost devoid of fats¹. If such, or similar, precautions are not followed, early vomiting, defective absorption of the dye, or delayed entrance of the dye-laden bile into the gallbladder may result in absence or faintness of the shadow when the viscus is normal. Unless the roentgenographic technic is correct, the shadow of the gallbladder may be obliterated by movement or overhard rays, or the organ may not be included in the region exposed. If the shadow is not dense, it may be concealed by gas or fecal material in the bowel. Extraordinary caution must be used in adjudging a shadow to be faint, for under normal conditions the density is affected by numerous variable factors and a standard cannot be established. Unless the shadow is so delicate that it can scarcely be discerned and its borders can be traced only with difficulty, it should be considered normal. Always it should be judged by its best appearance in the successive films not by its worst appearance. But the qualified roentgenologist is aware of these and of many other pitfalls, and only the inexperienced examiner is likely to be entrapped by them.

If there is a lingering suspicion that the normal gallbladder sometimes behaves eccentrically because of unexplainable inhibitions, substantial grounds for such mistrust are hard to find. Certainly when the technic of cholecystography is without flaw, the gallbladders of normal persons almost invariably respond normally to the test, and in the apparent exceptions the roentgenologist usually assumes that he, not the test, has erred.

At one time some roentgenologists were confident that various diseases of other organs might interfere with the ability of the gallbladder to receive and concentrate bile. Listed among them were duodenal ulcer, diabetes, exophthalmic goiter, pernicious anemia, cancer or ulcer of the stomach, low basal metabolism and obesity. Duodenal ulcer, diabetes and exophthalmic goiter were at first regarded as especially likely to impair the validity of the cholecystographic test, but with further investigation it appeared that they were far less common causes of deception than had been

supposed. An incomplete canvass of our own cases indicated that the incidence of cholecystographic evidence of impaired function, or of other disease of the biliary tract among patients who also suffered from any of the diseases or conditions mentioned, was even lower than such incidence among all patients examined, except perhaps in cases of diabetes and obesity, and possibly in cases of pernicious anemia and exophthalmic goiter. Further, when patients who had any of these concurrent diseases had been operated on, the conditions found had agreed closely with the cholecystographic data. However, because patients having these disorders are seldom sent for operation on the gallbladder unless there are marked symptoms of disease of the biliary tract in which event such disease is likely to be found, conclusive proof as to the influence of concurrent disorders on the function of the gallbladder is lacking, and as those named have been under suspicion, whether justly or unjustly, it is entirely proper for the clinician to take account of their potential effect in any case. A lesion causing marked pyloric or duodenal stenosis may retard evacuation of the dye, thus delaying absorption of the compound by the bowel and hence delaying its appearance in the gallbladder beyond the time of examination, but in such a case it is improbable that the clinician will fail to surmise the presence of obstruction or neglect to make appropriate investigation. Congenital absence and transposition of the gallbladder are such rare sources of error that they require only passing mention. Carcinoma of the pancreas may mechanically obstruct the common duct, but this is among the rarer diseases.

Impairment of hepatic function by disease of the liver, such as carcinoma or cirrhosis, would seem theoretically to be an effective cause of error in cholecystography. But Graham, Cole, Copher and Moore² have pointed out that normal cholecystograms have been found in the presence of retention of dye as high as 50 or 60 per cent in the blood stream thirty minutes after injection. However, they considered it reasonable to suppose that, if damage to the liver became sufficiently extensive, the amount of dye passing through would be inadequate for the production of a shadow by concentration in the gallbladder. It may be that roentgenologists have been inclined to underestimate the effect of hepatic damage on the cholecystogram, but their experience and the results of experimentation indicate that this effect can easily be overestimated.

On the whole, notwithstanding the many possible causes of absence or faintness of the shadow of the gallbladder, other than disease of the biliary tract, the percentage of errors from these sources, as proved by operation, has not been large, and it is to be doubted that the percentage in cases in which operation has not been performed would be materially larger.

Obviously, the reliability of cholecystographic data relative to patients whose symptoms do not warrant surgical intervention cannot be determined with finality except by subjecting a large number of such patients to cholecystectomy, and that is unthinkable. Even the most critical comparison of clinical with cholecystographic observations relative to patients not operated on cannot be decisive, for there are wide variances in the individual experience of clinicians, in their skill in eliciting the anamnesis and physical observations, in their degree of care in recording data, in the extent to

DR. WALTER B LANCASTER, Boston The subject is obviously one of many sides and the solution is not simple, because myopia is due to a number of causes acting together. One man will emphasize one cause, and another will emphasize another. The causes may be grouped into two classes: the local causes in the eye and the causes that depend on hereditary and general hygienic health conditions. It is important to urge the parents and nurse to guide the habits of the child and to teach him the proper method of holding the book, especially of holding the book farther away. However, in a family in which myopia is hereditary one child grows up myopic, and then the next one comes along and he also develops myopia. So one wants something more to do. Many have tried Dr. Wiener's method of epinephrine. Some have tried Dr. Luedde's method of atropine in one eye. I am not sure whether he has published a report on that, but he has tried it for some years. It is based on the belief that convergence is to be combated. It seems to me that convergence is an important factor. What can be done to diminish it? Using atropine in one eye may in some cases suffice to favor suffusion and do away with binocular vision and allow the eye to diverge instead of converge but if suppression with divergence is a good thing to produce, why not go a step further and use not only atropine in one eye but also cover it with the crinkly glass that is now available and so much less conspicuous than a ground glass or a black glass before one eye and yet effectively cuts down the vision? I have been using this method. It will take a long time to determine its value so I am asking that some ophthalmologists try it. Perhaps five or ten years from now some one will have some more data.

DR. EDWARD JACKSON, Denver The discussion has shown that the problems of myopia may be approached from very different points of view. It is a large subject and it requires such studies as Dr. Snell has made and as Dr. Tooke has made and suggested, and all the others. They will have to be brought together and coordinated before any general conception of the whole subject is possible. The matter of heredity has not been doubted at all. Immediately there arises in my mind a family in which the father and mother and the four children were myopic. This would probably have occurred even if they had been started to school with glasses or if glasses had been put on before they went to school. A former theory, which was frequently put forward before much was understood about the process of evolution, was that myopia was a preparation of the race for the use of the eyes for close work. I think that the statistics will show that perhaps 999 out of 1000 or perhaps only 99 out of 100 are born hyperopic. The size of the eyeball, its length, the curves of the refracting surfaces all indicate that those eyes must be expected to be hyperopic and that they are more highly hyperopic than the eyes ordinarily encountered at school age. The vision of children certainly is not complete at birth, or within a year or two afterward. But early they begin to be interested in objects that they can seize in the hands and bring as close as they please to the eye, in that way they get a large enough image to see even if they do not have very good vision. Practically all children come to school age with the habit of looking at near objects too close to their eyes for complete accommodation and with more convergence than they ought to have after they get to working in school. Every year I see some children having trouble with their eyes who on examination are found simply to be holding the print too close to their eyes. The only way to meet this situation and control it is to test the child repeatedly with very fine figures by bringing the card closer and closer to the eye until the child begins to back off, that is, give it a lesson that it is easier for the eye to see things farther away. Then if the mother is taught that she must watch the child with reference to this, one will get rid of the excessive convergence of infancy. It is new to me that the domestic animals are found to be nearsighted. They have deficiency of vision and they lack the full foveal vision that human beings have. Generally the lower animals have hyperopia. They may occasionally have myopia. The statistics with reference to savage races show that they are nearly all hyperopic. I think that Dr. Randall's statement has never been controverted that hyperopia cannot be "healthfully outgrown." The myopic eye is diseased when it becomes myopic.

CHOLECYSTIC DISEASE

A COMPARISON OF THE CLINICAL WITH THE
CHOLECYSTOGRAPHIC DATA CONCERNING
500 PATIENTS NOT OPERATED ON

B. R. KIRKLIN, MD

AND

THOMAS W. BLAKE, MD

Fellow in Radiology, the Mayo Foundation
ROCHESTER, MINN.

The reliability of cholecystographic data when subjected to the test of operation and pathologic examination has been proved repeatedly. For example, of 4,676 patients examined by cholecystography in 1932 at the Mayo Clinic, 732 were operated on, and the cholecystographic report, whether positive or negative, was confirmed in 696 (95 per cent) of the cases. Among 287 patients whose cholecystograms were normal and who were operated on chiefly for diseases other than of the gallbladder, surgical exploration confirmed the cholecystographic diagnosis in 257 (89.5 per cent). Of 445 patients concerning whom cholecystographic data were positive, 439 (98.6 per cent) had disease of the biliary tract. Comparable statistics have been reported by many other roentgenologists, so that the trustworthiness of the method, so far as proof by operation goes, is well established and generally accepted.

Occasionally, however, the question as to patients not operated on is raised, the implication is that, as only those patients who give marked symptoms of disease of the biliary tract ordinarily are subjected to operation, the percentage of correct cholecystographic diagnoses may easily be high, but that, if all patients regardless of severity of symptoms were operated on, the record of cholecystography might be less brilliant. Those who raise the question are not disposed to doubt cholecystographic evidence of gallstones or tumors, even in the absence of symptoms, but intimate that in other instances cholecystography is perhaps merely a procedure of confirmation and not of independent diagnosis, that often the cholecystographic data are not in consonance with the clinical facts, and that mere impairment of function of the gallbladder, as shown by cholecystography, is not of itself significant of disease of the biliary tract.

With respect to such intimations, the concession must be made that cholecystography is primarily a test of function of the gallbladder at the time of examination and that it is a direct method of diagnosis only when gallstones, calcific deposits in the bile or in the walls of the gallbladder, tumors or deformities of the gallbladder are demonstrable. It will also be admitted frankly that the roentgenologist cannot determine absolutely whether impaired function alone, as indicated by absence or faintness of the dye shadow, is attributable to disease of the biliary tract, to disease of other organs directly or reflexly affecting the ability of the gallbladder to receive and concentrate dye, or to conditions unrelated to disease. Notwithstanding these considerations, since thousands of operations have proved that disordered function usually is a result of disease of the biliary tract, as a rule it is far safer to draw this inference than to assume that the cholecystographic indications of impaired function are probably attributable to other causes.

which they are influenced by the cholecystographic report, and in the particular factors they deem necessary for the diagnosis of disease of the biliary tract, and a similar, although less pronounced, variance in the interpretation of cholecystographic phenomena obtains among roentgenologists. Nevertheless, such comparison is the sole available method of approach, and we have attempted to make an analysis of this sort.

The material comprised the records of 500 patients examined both clinically and cholecystographically at the clinic but not operated on. In 200 of the cases no shadow of dye had been discernible, and a report of nonfunctioning gallbladder had been made, in 100 the shadow of dye had been only faintly discernible, and a report of poorly functioning gallbladder had been made, in 200 the cholecystographic response had been normal and had been so reported.

The records were not selected but those of each group were taken consecutively as they appeared in the files of the Section on Roentgenology. Those patients who had nonfunctioning, or poorly functioning, gallbladders were examined in 1933 and 1934, and those who responded normally to the test were examined in the final weeks of 1934. Clinical examinations had been made by consultants and their assistants in the various sections of the clinic, and in most cases more than one consultant had seen the patient and had participated in the diagnosis. Cholecystographic examinations had been made after oral administration of the dye according to a rigid technique described heretofore, and interpretations had been made alternately by four consultants in the Section on Roentgenology.

In 185 (92.5 per cent) of the 200 cases in which there were nonfunctioning gallbladders, according to the cholecystograms, a clinical diagnosis of cholecystic disease was made. Among the fifteen exceptions, a questionable diagnosis of cholecystic disease was made in one instance, the cholecystographic report of nonfunctioning gallbladder was recorded without comment in two and disease of the biliary tract was not mentioned in twelve. Further, among these twelve a diagnosis of cirrhosis of the liver was made in eight and a low basal metabolic rate was emphasized in one. On the other hand, among the 185, diabetes was also diagnosed in three, cirrhosis of the liver in two, pernicious anemia in two, hyperthyroidism in two, duodenal ulcer in five, and a low basal metabolic rate was given special note in two.

In eighty-one (81 per cent) of the 100 cases in which there were poorly functioning gallbladders, a clinical diagnosis of cholecystic disease was made. Among the nineteen exceptions were one case in which one of the consultants held the opinion that the gallbladder was at fault and should be removed, five in which there were various degrees of doubt as to the presence of cholecystitis, three in which the cholecystographic report was cited without comment, and ten in which disease of the biliary tract was not mentioned. Moreover, among the nineteen cases excepted, a diagnosis of duodenal ulcer was made in one and a low basal metabolic rate was emphasized in one. However, among the eighty-one cases in which disease of the biliary tract was considered to be present, diabetes was also diagnosed in three, hyperthyroidism in three, duodenal ulcer in six, and cirrhosis of the liver in one.

In 188 (94 per cent) of 200 cases in which there were normally functioning gallbladders, disease of the biliary tract was not mentioned by the clinician in the record. Among the twelve exceptions the clinician

made a definite diagnosis of cholecystic disease in three cases and noted the possibility that such disease might be present in nine. Again, among the exceptions the additional diagnosis of duodenal ulcer was given in one instance and of pernicious anemia in one. But among the 188 cases in which it was considered that disease of the biliary tract was not present, duodenal ulcer was diagnosed in twenty-four, diabetes in two, cirrhosis of the liver in one and pernicious anemia in one, and the low basal metabolic rate was stressed in four.

Thus the results of this study do not confirm any mistrust that the test of function by cholecystography, as a basis for judgment whether the gallbladder is probably diseased or normal, is less reliable in cases in which operation is not performed than in cases in which it is performed. On the contrary, in 90.8 per cent of these 500 cases the cholecystographic report was in consonance with the final clinical opinion, and this closely approximates the accuracy of cholecystography as proved by operation.

But, if this percentage is fairly representative, it is to be hoped that no one will hastily conclude that cholecystography is superfluous and that the symptoms and signs, together with the results of other tests, are consistently sufficient for the diagnosis or exclusion of disease of the biliary tract. Surely, quite aside from its revelation of gallstones and tumors, cholecystography must have considerable value, both in direct and in differential diagnosis, else it would not be employed as freely as it is. In this appraisal of cholecystography there is no subtle suggestion that the clinical examination can be discarded or that the two methods are competitive. Roentgenologists have always insisted that the cholecystographic data should invariably be weighed in the light of the clinical facts. When the respective conditions found are inconsistent, it is the acknowledged privilege and duty of the clinician to consider whether technical or interpretive errors may have been made or whether disease elsewhere may have affected the functional behavior of the gallbladder, or whether in spite of a normal cholecystogram, the biliary tract may nevertheless be diseased. Further, however valid the cholecystographic signs of impaired function may be as indications of disease of the biliary tract they will not determine whether the disorder is transient or chronic, mild or severe, or whether it is the cause of the patient's chief complaint, and determination of these matters rests solely with the clinician. In short, the roentgenologist and the clinician are obliged to cooperate and neither will profit from entertaining captious doubts as to the efficiency of the other's method.

ABSTRACT OF DISCUSSION

DR. I. S. RAVDIN, Philadelphia. Any laboratory examination that can be proved correct in its interpretation in 95 per cent of instances needs no further justification. It should be admitted, however, that in its universal application by roentgenologists the results of cholecystography are not nearly so good. The excellent results reported in the paper are due to the great care in the administration of the dye and in the roentgenographic procedure factors that were stressed by Graham and Cole when the method was first described. The suggestion that even faint shadows be considered an indication of normal function is not in accord with known facts in regard to gallbladder function. Studies of the gallbladder bile in gallbladder disease in a large number of patients have conclusively demonstrated that all degrees of concentration may take place. A faintly visualized gallbladder may be due to the failure of the gallbladder to concentrate the dye adequately, and such a gall-

bladder is in no sense normal in its function. The varied terminology now being used by roentgenologists for reporting the results of cholecystographic study should be discouraged and an attempt should be made to develop a standard nomenclature for reporting the results of study. The authors have exercised such caution in the determination of the status of what may well be called borderline cases that no possible exception can be taken to their statements. It is in this group that full cooperation between the roentgenologist and the clinician is necessary. I hope that before long some one will publish the cholecystographic data from a group of noncalculous cases in which gallbladders have been removed partly as a result of the cholecystographic evidence and compare the results of roentgen study with the end results of operation. It is my impression that in this group regardless of the cholecystographic evidence the end results of operation are not good.

DR B R KIRALIN, Rochester, Minn. Did I understand Dr Ravdin that that was the recognition of the stones in all the gallbladder cases or stones in a certain group?

DR I S RAVDIN, Philadelphia. That was a consecutive series of 165 cases. The stones were frequently present as positive shadows when the concentration of shadow was below 5 per cent. It gave no information as to where the stones might be visualized.

EXPERIENCES IN LEG LENGTHENING

E C JANES, M.B. (TOR.)
HAMILTON, ONT.

The subject of leg lengthening is of vital importance to those patients who are unfortunate enough to have a short extremity. They must wear an unsightly and heavy lift of some sort, or they must be content to walk with an awkward gait and bear with what fortitude they have the compensatory deformities that inevitably develop.

If a lift is not worn to equalize the length of the legs, the pelvis is constantly tilted, and a scoliosis develops which may seriously handicap the patient. A lift as well as being unsightly means extra weight on an already weakened extremity.

What doctor has not had patients ask if anything can be done to correct the shortening of an extremity? What doctor has not felt at least a little guilty because

Fig 1 (case 1)—Appearance after lengthening was complete but with the apparatus still in position.

of the patients' disappointment if the answer is in the negative? It is necessary and just that all those interested in orthopedic surgery make themselves familiar with the best methods of correcting inequality in the length of legs and be prepared to offer their patients the benefits thereof.

Codivilla¹ and Putti² showed that lengthening was a practical procedure—that it must be done gradually, and that skeletal traction and countertraction should be used. They proved that it was the fascial structures of an extremity that provided the greatest resistance to lengthening and that blood vessels and nerves would tolerate considerable gradual extension.

It remained for Abbott³ to devise an apparatus and a surgical technic that was practical. Abbott should get full credit for giving this work the necessary stimulus on this continent. He described a form of osteotomy that left considerable bone surface in contact when lengthening was complete and he devised an apparatus to maintain accurate alignment as well as extension. Various modifications of his technic and apparatus have been reported but the fundamentals are not changed and might be listed as follows:

Fig 2 (case 1)—Five and one-half years after operation showing very little evidence that any operation has been performed on the tibia.

- 1 Skeletal traction and countertraction
- 2 Slow and gradual lengthening
- 3 A form of osteotomy that leaves considerable bone surface in contact when lengthening has been completed
- 4 Wide division of fascia
- 5 Some form of stabilizer to maintain accurate alignment of fragments
- 6 Rigid surgical technic
- 7 Postponing of stabilizing operations until lengthening has been completed

The purpose in this presentation is to stimulate interest in the subject and to report a few cases in which leg lengthening has been performed. The cases chosen illustrate shortening due to various causes and several difficulties that may be encountered. From these experiences one may form an opinion as to what types of cases are suitable for leg lengthening and also what might be considered the ideal case for this procedure. Details of technic and apparatus will not be described, because space does not permit. A modified Abbott machine was used in all cases.

REPORT OF CASES

CASE 1—D K., aged 15 years, had infantile paralysis at 18 months of age, followed by extensive paralysis of the left leg including the quadriceps. The patient walked with the aid of crutches and a long leg brace until the age of 14 years.

In November 1928 triple arthrodesis was done with fixation of the achilles tendon and transplantation of the semimembranosus tendon to the patella.

In May 1929 lengthening of the left tibia of 2¾ inches was obtained. The leg was supported in a plaster cast for six months. The patient now walks well without any appliance, and the legs are equal in length.

- 3 Abbott L C. The Operative Lengthening of the Tibia and Fibula. *J Bone & Joint Surg* 9: 128-152 (Jan) 1927.

CASE 2—K D, a girl, aged 15 years, had atrophy of the right leg due to infantile paralysis. The right leg was 2 inches shorter than the left.

In July 1932 lengthening of the right tibia of $2\frac{1}{4}$ inches was obtained. The leg was supported in a plaster cast for six months. Moderate infection developed but cleared up without trouble. At present she walks well. Her legs are equal in length.

Fig 3 (case 1)—Apparatus in position

CASE 3—J I, aged 21, had $1\frac{1}{2}$ inch shortening of the right leg, as the result of malunion of a fracture of the right femur five years before.

In October 1932 lengthening of the right tibia of $1\frac{1}{2}$ inches was obtained. The leg was supported in a plaster cast for about seven months but the patient was able to return to work in four months. Moderate infection developed necessitating the curetting of a sinus from the tibia in December 1933 after which the infection cleared rapidly.

Fig 4 (case 4)—Condition A in April 1930 B in May 1935

In January 1930 a Helferichs osteotomy was performed to allow straightening of the knee without loss of length.

In March 1930 lengthening of the left femur of 3 inches was obtained. Altogether after operation the left foot was $5\frac{1}{2}$ inches closer to the floor, 3 inches by lengthening the femur and $2\frac{1}{2}$ inches by osteotomy of the knee, and she now requires a 2-inch lift built into her shoe to walk comfortably.

One and a half years after the lengthening she fractured the left femur through the same area in which the lengthening

had been done, but union took place in the usual length of time. There was mild infection about the lower end of the upper fragment after lengthening.

CASE 5—W K, a youth, aged 17, had 4 inch shortening of the left leg, due to healed tuberculous arthritis of the left hip joint.

In October 1932 lengthening of the left tibia of 2 inches was obtained. Bony union in the upper part of the tibia was delayed and about six months after operation a fracture occurred through this area. Healing still did not take place, so a bone graft was placed across the fracture in September 1933. Healing then progressed rapidly. At present he walks quite well with about a $1\frac{1}{2}$ inch lift inside the left shoe.

COMMENT

The average lengthening obtained was approximately $2\frac{1}{4}$ inches. Troublesome infection occurred in three cases but no serious osteomyelitis developed. Although fairly satisfactory results were obtained even in these cases one feels that more lengthening might have been obtained if infection had not been present. This was

Fig 5 (case 4)—Shortening in January 1930

particularly true in cases 4 and 5. Safe bony union was slow in all the cases. It was necessary to keep the leg supported for at least six months, and about eighteen months in case 5, in which a bone graft was required. There was some trouble because of tilting of the fragments during lengthening in two cases, and the apparatus is now provided with a stabilizer to correct this defect. The results are gratifying to the patients in spite of the discomforts and dangers, and all of them feel that the time was well spent. The entire period is not necessarily wasted because further rehabilitation is possible during convalescence. Two of these patients took courses in shorthand and stenography during their treatment and have subsequently found remunerative positions.

In these cases the operation was performed for shortening due to (1) infantile paralysis, (2) healed tuberculosis of the hip joint, (3) malunion of fracture and (4) growth disturbance due to destruction of the epiphyseal lines.

One hesitates to be dogmatic about the amount of shortening necessary to justify operation, but I feel that

it should never be done for less than $1\frac{1}{2}$ inches. Each case, of course, should be individualized, and the psychologic effect of a short extremity and an unsightly limp on both the patient and a prospective employer must never be forgotten.

If the shortening is due to infantile paralysis, and the patient is able to walk without a brace—perhaps after various stabilizing operations—leg lengthening should be done, but if the quadriceps is paralyzed and cannot be replaced a long leg brace is usually necessary, and lengthening would appear to be too formidable for the benefit to be obtained. The ideal type of case would be one in which the extremity is normal except for its length. This condition is most closely approximated when shortening is due to malunion of a fracture or to healed tuberculous arthritis of a hip joint.

Apparently the blood vessels and nerves will allow the extension necessary, provided they are stretched

Fig 6 (case 4)—Appearance in May 1935 with the cumbersome apparatus worn before lengthening and the shoe worn at present

very slowly. If lengthening is too rapid, the foot may show temporarily a little coldness and numbness.

The operation must not be undertaken lightly. It should be done only in a hospital, where rigid surgical technique and adequate after-care can be obtained. The surgeon should have some mechanical inclination and sufficient training in major bone surgery.

Patients who undergo the operation should be prepared to give up about six months. The ideal time in the patient's life is at 15 or 16 years of age, when growth is nearly complete but before the wage earning period. There is no reason, however, why the operation cannot be performed at practically any age.

The entire process is a formidable one, but, judging from my own experience and the reported experience of others, it is a quite justifiable procedure and should be added to the armamentarium of all those who undertake the surgery of cripples.

250 Main Street East

ABSTRACT OF DISCUSSION

DR PAUL N JEPSON Philadelphia My comment on Dr Janes's procedure is one of caution. The operation with its pitfalls and objections, was first clearly discussed by Dr Abbott several years ago. There are several avenues open to infection. The one important objection to the operation is that the bone marrow is widely opened. Some irritation is caused by the introduction of the pins or wires and these bony openings are the avenues by which infection may enter. The procedure in competent hands works well but the wounds must be watched carefully and must be carefully dressed. It has been suggested that a series of simple single-step osteotomies be done in place of this procedure. Such an operation has been done by means of a long slanting osteotomy notching for the required length and prying the bones into place. Only a limited amount of leg lengthening can be obtained, namely, three-fourths inch and according to the amount of shortening present the procedure may require several operations, which in itself is a definite objection. For this reason, unless the conditions under which it is performed are adequate the operation ought not to be undertaken. To me it is a formidable procedure. The cases presented by Dr Janes are remarkably good ones.

DR JAMES A DICKSON Cleveland Most excellent and satisfactory results can be obtained in bone lengthening operations by means of the Abbott technique and its modifications. It is a formidable surgical procedure, and each case must be given serious consideration before the operation is undertaken. The patient requires long hospitalization and careful supervision for from six months to a year and sometimes even longer, hence the economic as well as the surgical difficulties must be considered thoroughly.

In well chosen cases the final result more than compensates for these difficulties. As Dr Janes has pointed out this operation should not be considered unless the shortening amounts to $1\frac{1}{2}$ inches or more. When there is a flail extremity and the patient is going to have to wear a brace anyway the lengthening operation should not be considered. When there is a weakness of the gluteus medius and the patient has to walk by deviating the spine to the opposite side in order to bring the leg forward at least $1\frac{1}{2}$ inches of shortening is required to enable the patient to

Fig 7 (case 5)—Condition in March 1933 showing a weak bridge of bone supporting the leg and in November 1933 showing the fracture of the bone graft in place

Fig 8 (case 5)—Well healed and strong, tibia in May 1935

PARAFFIN IN BLADDER—KATZEN

Jour. A. M. A.
Nov. 2, 1935

walk with an optimal gait. It is advisable therefore to experiment with various heights of lift on the shoe in every case of poliomyelitis in order to determine which height gives the best walking gait. In this way the optimal degree of lengthening can be determined before operation. In view of the fact that in spite of all precautions a certain degree of valgus deformity may result during the lengthening procedure, it would probably be better to perform the lengthening operation first and attend to stabilizing procedures later. Probably the most dramatic results in leg lengthening are obtained when the shortening is caused by something other than poliomyelitis such as tuberculosis of the hip or knee. In the healed tuberculosis of the hip Dr. Janes did a lengthening of the tibia rather than of the femur. Successful lengthening of the femur can be accomplished by weights alone with the line of pull in the axis of the upper fragment of the femur. In tuberculosis of the knee, when the roentgenogram shows that the shortening is due to a fusion of the tibial or femoral epiphysis, the legs may be equalized by the Phemister operation for fusion of the same epiphysis on the well leg. The type of operation to be used in equalizing the length of the extremities in this type of case should be chosen also according to the structural type of the individual.

trouble is liable to come later on when lengthening has been started. There has really been very little shock from the actual application of the apparatus. Dr. Anopol has shown some modifications of technic and apparatus that should prove interesting.

Clinical Notes, Suggestions and New Instruments

PARAFFIN FOREIGN BODY IN THE BLADDER
PERRY KATZEN, M.D. BROOKLYN

Foreign bodies in the urinary bladder are by no means uncommon, all varieties of objects having been described in the literature. Such articles composed of wax, however, seem to be of comparatively rare occurrence. The following case is reported as an instance of the nonoperative removal of such a foreign body.

REPORT OF CASE

F. S., an unmarried white man, aged 21 years, consulted me Nov. 3, 1934, giving the following history. Three days previously while at a house party, he and several companions became intoxicated and as a practical joke his "friends" inserted into his urethra a paraffin candle measuring approximately 2½ inches in length and one-fourth inch in diameter. The patient stated that he immediately felt the candle slip into his bladder. Twelve hours later there developed frequency of urination, dysuria, tenesmus and terminal hematuria. At the time of examination he was voiding every thirty minutes with severe pain. During the preceding twenty-four hours he had noticed that the urine was quite cloudy and bloody. The previous history was irrelevant, there was no history of venereal disease.

Physical examination was negative except for tenderness on palpation over the suprapubic region. The temperature and pulse were normal. The urine was grossly bloody, and on analysis the reaction was alkaline, the specific gravity was 1.016, there was a trace of albumin, there was no dextrose, many pus cells and red blood cells were present and there were many gram negative bacilli having the morphology of *B. coli*. On roentgenologic examination of the urinary tract both kidneys appeared normal in size, shape and position. There was no radiographic evidence of calculus or foreign body.

Cystoscopy revealed intense inflammation of the entire bladder mucosa and scattered throughout were many hemorrhages. Floating near the vault was a white paraffin candle of a size corresponding to that described by the patient. It was divided into three segments attached to one another by the wick, but apart from that its form had not been altered as a result of its three-day stay in the bladder; the wax not appearing softened and the spiral design of the candle being well preserved. Several attempts were made to grasp the candle with a cystoscopic forceps, but the candle repeatedly slipped away as the jaws of the forceps closed down on it and further efforts at removal were abandoned at that sitting. Methenamine and ammonium chloride were prescribed.

The patient was seen again the following day; his symptoms were unchanged and the urine was still bloody. A Young's cystoscopic rongeur was introduced into the bladder, the cystoscopic appearance was the same as noted the previous day. With considerable difficulty, owing to the elusiveness of the floating wax, several pieces of the candle were removed with the rongeur, but with each bite of the latter numerous small fragments of the candle were broken off and remained in the bladder so that at the end of the procedure probably half of the original amount of paraffin could still be seen floating near the bladder vault. A portion of the wick also remained, attached to several pieces of wax.

To effect the removal of the remaining wax it was decided to employ liquid petrolatum as a solvent, as first suggested by Harris.¹ Accordingly, 100 cc. of warm sterile liquid petrolatum was instilled into the bladder through a rubber catheter.

Fig. 9 (case 5)—Appearance A before and B after the lengthening

DR. GEORGE ANOPOL, New York. My purpose is to bring out a more simplified method in holding the fragments in line and during their traction making the patient more comfortable during his stay in the hospital and eliminating any trauma to the operated site in case of any emergency or moving the patient from the bed to the chair. Most of the other appliances require the patient to be kept in bed. The method I use consists of two isometric parts. Each consists of two telescoped tubes, the inner one being graduated and two posts, one at the upper and one at the lower end with the traction so arranged that when they are pushed apart the distance between them is reported by the calibration on the inner tubes. This eliminates the distance roentgenography with pieces of metal and then calculating the distance obtained. The apparatus is combined with plaster-of-paris technic.

DR. E. C. JANES, Hamilton, Ont. I quite agree that the warning about a little caution regarding this operation is timely. Still any one doing surgery of cripples should be prepared to take a fair amount of responsibility. It must be remembered that these children will at times be willing to undergo a great deal of risk and discomfort to have their deformities corrected. I have not been much impressed by the danger of shock from the operation itself in my cases. The

¹ Harris, Augustus A. Case of Paraffin Foreign Body in the Bladder. *M. J. & Record* 134: 372 (Oct. 21) 1931.

and the suprapubic region was massaged thoroughly. The patient was instructed to refrain from urinating as long as possible and to massage over the bladder at intervals.

The following day he felt better, the frequency and dysuria had diminished, although gross hematuria was still present. The bladder was irrigated with 1 5,000 mercuric oxycyanide solution and 100 cc of warm, sterile liquid petrolatum was again instilled, followed by massage over the bladder region. The same treatment was instituted the next day. On each occasion the patient was able to retain the oil for from two to three hours without any evident bladder irritation.

The patient was reexamined two days later, at which time he stated that there was considerable lessening of the urinary distress and that he now noticed only occasional slight hematuria. On cystoscopy there was still evident a severe hemorrhagic cystitis, but it was less marked than previously. Neither wax nor wick was visible, the latter having apparently been passed unnoticed by the patient.

During the following month the bladder was irrigated twice a week with 1 4,000 solution of acriflavine base accompanied by a gradual clearing of the urine. The patient was last examined Dec. 8, 1934. On that date he was entirely free from symptoms, the urine was crystal clear, and cystoscopy revealed a normal bladder mucosa.

COMMENT

Paraffin acts as a marked irritant to the bladder mucosa, provoking a violent hemorrhagic cystitis within twenty-four hours. Occasionally it may serve as a nucleus in the formation of a vesical calculus. The prompt removal of such a foreign body is therefore clearly indicated.

In most cases it should not be necessary to employ cystotomy for this purpose. At times one may succeed with the use of the cystoscopic forceps, Young's rongeur, or the cystoscopic lithotrite, but there is great difficulty if not complete failure in such procedures. The wax constantly slips away from the jaws of the instrument and floats high in the bladder. If the wax finally is grasped, it crushes very readily into many fragments on account of its friable nature, making repeated instrumentation necessary. In a severely inflamed irritable bladder which bleeds easily, this procedure is far from desirable.

Various methods of dissolving wax in the bladder have been employed. Heat alone applied by means of bladder irrigations as hot as could be tolerated was used by Boss² with only partial success in a patient with a candle in the bladder. After twenty-two days of treatment several pieces of wax were still present.

Lohnstein³ in 1907 was the first to describe the use of chemical solvents. A patient with a stearin candle in the bladder was given an instillation of 15 cc. of benzene and retained it for forty-five minutes. This was immediately repeated with 25 cc. which the patient could retain for only ten minutes. The same treatment was instituted the following day. Although this was effective in dissolving the wax, there ensued symptoms of benzene poisoning as well as considerable vesical irritation. Weisz⁴ also employed benzene but he first injected 120 cc of water into the bladder, so that the trigon which was the part most severely inflamed in his patient, would not come in contact with the benzene since the latter floated on the water.

A number of other solvents have been used. Caples⁵ after three unsuccessful attempts at removal with the cystoscopic rongeur of a paraffin candle lodged in the vesical neck, dissolved this foreign body by bladder instillations of 33⅓ per cent gasoline in liquid petrolatum at 110 F. giving seven such injections over a period of three days. The same solvent was effectively used by Melen⁶ in a bladder containing a wax drawing-crayon using six instillations. Hottinger⁷ in a boy with a mass of beeswax in the bladder was able to remove

part of the wax through the operating cystoscope and dissolved the remainder with xylene, injecting water into the bladder first and following with 12 cc. of xylene, which was retained for four hours. Xylene was also employed successfully by Geyer,⁸ who used 50 cc. and repeated this instillation five days later.

The use of liquid petrolatum, described by Harris, impressed me with its effectiveness and freedom from irritation. Harris injected 100 cc of warm liquid petrolatum into a boy's bladder which contained part of a paraffin candle. This was followed by massage over the bladder and the application of external heat by means of hot sitz baths and a hot water bag held over the suprapubic region. Four such instillations were given twenty-four hours apart, each being retained for three or four hours. Most of the wax was dissolved after two injections, the wick was passed spontaneously after the second instillation. Several days after the last treatment cystoscopy revealed only a few patches of mild cystitis, with no evidence of foreign body.

CONCLUSIONS

1 The removal of paraffin from the bladder should not require cystotomy or operative cystoscopic procedures.

2 Liquid petrolatum is an effective, nonirritating solvent for such foreign bodies. In the case of paraffin candles, if the wick is not voided spontaneously, it may easily be removed with the cystoscopic forceps.

A CASE OF AUTHENTICATED FERTILITY IN A MAN AGED 94

FRANCES I. SEYMOUR, M.D., NEW YORK; CHARLES DUFFY, M.D.,
NEW BERN, N. C.; AND ALFRED KOERNER, M.D., NEW YORK

The patient here studied was born on a farm in North Carolina in the year 1840. His entire boyhood was spent in the usual pursuits of a farm boy until at the outbreak of the war between the states he joined the Confederate troops. After some time in the army he was put into a grinding mill, which turned out flour for the soldiers. The end of the war found that he had not been in any battles. The war over, he returned to farming. In 1872 he married. His wife lived until ten years ago, bearing him sixteen children, of whom six are living and well, the oldest being 63 and the youngest 33. Evidence that the stock was good is further supported by the fact that there are thirty-eight grandchildren. Approximately a year ago our subject remarried, this time pledging himself to a widow of 27. A few weeks ago a child was born of this union, the father at this time being a little over 94 years old.

He has always been a man of outdoor habits. Except for an occasional cold and pneumonia eighteen years ago, he has been singularly free from illness. He has had no operations, accidents or hospitalization of any sort. He chews tobacco but does not smoke. Until a few years ago he drank considerable alcohol. On both his father's and mother's side, long life has been the rule, his mother dying at the age of 103. There has been a total freedom from familial involvement in any chronic diseases.

The general appearance of the patient is senile. He has a markedly wrinkled skin, brownish in cast, leathery in texture and having a considerable number of comedones. The angle of the jaw is distinctly of the senile type. On both eyes there are pterygia, the left being incipient. Arcus senilis is present and there are early cataracts on both eyes. The fundi present an interesting picture. The light reflex is considerably increased, the arteries appearing silver-wire and the veins being somewhat ampullated. The pupils react to light, though somewhat sluggishly. They are round and equal and respond to accommodation. There is no evidence of hippus, no deviation, no divergence, no enophthalmos and no exophthalmos. The ear drum is lusterless and opaque. A tonsillar tag is present on the left side. Most of the teeth are missing and there are several which are represented by roots only. Those which the patient retains are in poor condition.

⁷ Hottinger, R. Ueber Fremdkörper der Harnblase und ihre Entfernung. Cor. Bl. f. Schweiz. Aerzte 40:875 (June 14) 1919.

The subject is pigeon chested and has a slight kyphosis. His height is 5 feet 8 inches (173 cm) and his weight is 165 pounds (75 Kg). The heart is enlarged about the width of three fingerbreadths to the left and two fingerbreadths downward. The rate and rhythm are regular, there are no murmurs, and there is no dyspnea on exertion. The lungs present no evidence of pathologic changes. The radial arteries are pipe-stem in character. The pulse is regular, there being no variation in pressure and no arrhythmia.

The abdomen presents a rather surprising amount of good musculature, and there is no evidence of any herniation. The prostate is not enlarged. The extremities are not remarkable.

In general, the muscles of the body are well developed, firm, and in a good state of preservation. The cranial nerves were tested in detail, peppermint energine (a cleaning fluid) and ether being (among other things) the substances used in the sensory determination.

The first seven cranial nerves were normal both on sensory and on motor tests. The bone conduction was greater than the air conduction, phonation was good and the oculocardiac reflex was negative. The eleventh nerve showed no abnormality. The movement of the tongue was more pronounced to the right than to the left side. Its papillae were accentuated.

The patient's gait was normal. There were no tremors present. Coordination, both equilibratory, including the Romberg phenomenon, and nonequilibratory, was entirely normal. There was no evidence of aphasia, either motor or sensory. The diffuse tactile sense was hyperesthetic. The reaction to pain was hypesthetic, muscle sense being hyperesthetic, while both temperature and vibration were normal. Mentally the patient was entirely normal, his general behavior and cooperation being excellent, his emotional state was euphoric, and his orientation, memory, intelligence and judgment were very good.

Examination of the blood showed hemoglobin 85 per cent, white cells 6,500 and red cells 4,900,000. The blood clotting time was three and one-half minutes. The blood sugar was 115 mg per hundred cubic centimeters and a negative Wassermann reaction and gonorrhea fixation test were offered in further examination of the blood. A differential count of the white cells showed 44 per cent polymorphonucleocytes, 14 per cent large lymphocytes, 21 per cent small lymphocytes, 5 per cent monocytes, 3 per cent basophils, 2 per cent eosinophils and 11 per cent stab cells. The red cells showed some poikilocytosis, some variation in size and considerable achromia (about 30 per cent). The platelets appeared normal in number. The urine showed a specific gravity of 1.020, it was the color of light amber, its reaction was neutral, sugar and albumin were absent. Microscopic examination revealed a few amorphous crystals, an occasional epithelial cell, no casts, no red blood cells, and no pus. The specimen contained several cylindroid strands.

The seminal fluid was entirely within average limits in appearance, color and viscosity. The spermatozoa were of the average size, only 65 per cent of the customary number were present. Their conformation was entirely normal, and their motility was very great.

COMMENT

We have presented here a man of 94, the first instance within our knowledge in which fertility has been definitely and affirmatively checked up medically. We are confronted by an individual showing evidences of fine preservation coexistent with signs of advancing age, in whom the element of fertility seems practically unaffected. We have shown that in a case in which fertility is retained until very late in life, as here, the appearance of the sperm is indistinguishable from that of a young individual in the virile state. On the basis of the physical examination it is rather difficult to understand why a certain function of the body should be spared from the inroads of advancing age beyond those seen in the vast preponderance of human beings. This record tends to throw doubt on the doctrine sometimes advanced that hard work is inconsistent with fertility. It also may be considered to question the occurrence of and constancy of the menopause in the male.

To what benign influence this happy state is attributable must remain the subject of conjecture. Whether heredity, outdoor habits of life, particularly suitable tissue structure, or a mental state that finds itself in peculiar harmony with nature,

or whether any combination of the elements is intriguing speculation, to which, however, at present no definite answer can be given.

It is of the greatest interest in such cases to endeavor to isolate the element to which fecundity may be definitely ascribed so that it may be supplied in those cases in which a premature absence occurs. Whether such a substance is hormonal in nature, whether it is species specific, type specific or entirely individual is as yet not known. It does, however, seem that the familial tendencies of the individual and the soil on which the seed is planted are important factors that exhibit a certain amount of constancy on which dependence can be placed.

THE PHYSICAL CHARACTERISTICS OF DIATHERMY AND SHORT WAVE DIATHERMY MACHINES

ALLAN HEMINGWAY, PH.D.
AND

K. W. STENSTROM, PH.D.
Assistant Professor of Physiologic Chemistry and Professor of Biophysics, Resectively University of Minnesota
MINNEAPOLIS

An electric current produces heat when it passes through tissues, and this action has for a number of years been utilized by physicians for treatments of certain conditions. The apparatus used is referred to as the diathermy machine. The most important feature of this machine is that it delivers a high frequency current. This is the only type of electric current which can safely be passed through the body at high enough intensity to raise the temperature appreciably. Diathermy could not be developed until physics had advanced enough to make such currents available.

A method of producing high frequency currents to generate electromagnetic waves was discovered by Hertz in 1887. A few years later, in 1893, d'Arsonval discovered that a high frequency alternating current in passing through animal tissues would not stimulate the neuromuscular system to cause an electrical shock but would produce heat in the tissues. During the next few years apparatus was developed for the purpose of generating high frequency alternating current to heat the tissues for therapeutic purposes. The clinical use of diathermy at first developed gradually but became quite popular during the years 1905 to 1910. During the years 1910 to 1920 diathermy was enthusiastically used and favorable reports were numerous for many forms of disease. Since 1920 the use of diathermy has been subject to a more critical examination clinically, physiologically and physically, with the result that its characteristics, contraindications, dosages and uses are well known.

At the present time two types of diathermy machines are used to produce high frequency electric current which will pass through the tissues producing heat but no neuromuscular stimulation. These two types of machines will be referred to in this paper as the spark gap diathermy machine and the vacuum tube diathermy machine.

TYPES OF DIATHERMY MACHINES

The Spark Gap Diathermy Machine—This has been used for the past forty years. It is this type of machine which was first used by d'Arsonval and the earlier workers. During the operation of the machine, when a nonstimulating electrical current is being generated, there is electrical sparking at specially constructed spark gaps built within the machine. The electrical current that is produced by the machine and that passes through the patient oscillates back and forth in the electrical circuit which contains the patient. The oscillation of the current is very rapid, one oscillation lasting about one millionth of a second. The inability of this current to cause electrical stimulation is due to its rapid oscillation. The spark gap diathermy machine does not deliver to the patient a current that is continually oscillating. The current oscillates for a short time and then ceases. The oscillating period is followed by a pause during which no current flows. This in turn is followed by an interval in which an oscillating current again flows. This process of oscillation current—pause, oscillation current, pause—is repeated indefinitely until the switch is turned "off." The electric current is sent through the patient as a series of pulses separated by intervals in which no current flows. Each pulse consists of a train of oscillations. At the beginning of each train the current is high but during the oscillation interval the current decreases, each successive oscillation decreasing in magnitude until the oscillations cease as the magnitude becomes zero, when the pause between oscillation trains commences. With spark gap diathermy there would be several hundred to several thousand trains of oscillations and the same number of pauses per second. The curves in figure 6 are drawings made from oscillograms of actual diathermy currents. The curves show how the voltage, or the electromotive force which drives the current, varies during the passage of a diathermy current. The current varies in a manner similar to the voltage.

The majority of spark gap diathermy machines, but not all, produce an oscillating current which has a frequency of some value between one-half million and 2 million cycles per second. In using diathermy current of this frequency it is necessary to apply the electrodes tightly against the skin. This is necessary to insure good electrical contact. If the electrode fits loosely, sparking is likely to occur, causing a burn.

The Vacuum Tube Diathermy Machine—This has been developed into a practical therapeutic unit during the last ten years. The early machines of a decade ago were not practical, owing to the high cost of vacuum tubes and the short life of the tubes. During recent years vacuum tubes have been much improved mechanically and electrically, with considerable reduction in cost. At present the manufacture of these machines is increasing, but whether they are superior to spark gap machines for therapeutic purposes is a question.¹

The nonstimulating current delivered by these machines is a current that is oscillating continually. The stream of electrical charges, in the electrical circuit which contains the patient moves back and forth at a regular rate. There are no pauses between trains of oscillations as in spark gap diathermy. The type of current is similar to the alternating current used for lighting purposes except that it oscillates from 10,000 to 100,000 times faster than the lighting current.

Vacuum tube diathermy machines are of two different types, differing in the frequency of the diathermy current that they generate. One type of machine generates alternating current in the range usually covered by the spark gap machine, namely from one-half to two million cycles per second. This type of machine is generally used for surgical purposes. Another type is the so-called short wave diathermy machine. This machine generates diathermy current of a much higher oscillation frequency, the frequency range extending from 10 million to 100 million cycles per second.

Diathermy machines, while producing a nonstimulating diathermy current, also radiate energy in the form of electromagnetic radiation in a manner similar to a radio transmitting set in a radio station. The wavelength of the radiation depends on the frequency of the diathermy current. If the frequency is 10 million cycles per second, the wavelength of the electromagnetic radiation is 30 meters. If the oscillation frequency has

Fig. 1—Oscillographic tracings of a direct current, a continuous sine wave alternating current, and a damped sine wave alternating current.

a high value of 100 million oscillations per second, the wavelength of the radiant energy is 3 meters. As a consequence of this inverse relation between oscillation frequency of the electrical current and wavelength of the radiant energy the term "wavelength" is quite frequently used in place of "frequency." The exact relation is: oscillation frequency (cycles per second) \times wavelength (meters) = 300,000,000. The diathermy current from vacuum tube machines, which has a frequency of from 10 million to 100 million cycles per second, can be delivered to the patient in an unusual manner. This consists in placing the diathermy electrodes not in actual contact with the skin but at some distance from the skin surface. An air space of from one-half to 2 inches separates the metallic electrode and the skin. Used in this way a metallic electrode can be covered with an insulator and still be effective. On starting the diathermy machine the diathermy current passes from one electrode, across the air gap to the

¹ Mortimer Bernard and Osborne S. L. Tissue Heating by Short Wave Diathermy. Some Biologic Observations. J. A. M. A. 104: 1413 (April 20) 1935.

patient and then across the other air gap to the other electrode. The diathermy current is concentrated in the region between the electrodes. This method of applying the diathermy electrodes should prove valuable in treatment of regions of the body in which the surface is very irregular with bony projections and where it is difficult to apply an electrode by actual contact. It is then advisable to have the space between the electrode and the skin filled with a substance of about the same

Fig. 2—Typical condenser circuits

dielectric constant as the tissues (e. g., distilled water in a rubber bag with thin walls) in order to prevent overheating of these projections.

Another method of administering heat by diathermy is to surround the region to be heated by a coil of wire through which a high frequency current is passing. The high frequency current in the coil generates local "eddy currents" within the tissue. It is these localized currents which produce heat.

In choosing a machine of the vacuum tube type for diathermy treatments by electrodes not in actual contact with the skin it is necessary to have the machine conform to a certain standard if it is to be of value. The first requirement is that the machine must be able to deliver to the patient sufficient energy. Unfortunately, some machines are now being manufactured that are deficient in this energy requirement. It is necessary to deliver heat energy to the patient to raise the temperature of the tissues treated. These low power machines do not generate the required amount of heat. A second requirement is that the frequency of these machines for this noncontact method of placing the electrodes must be greater than 10 million cycles per second, otherwise this method of applying the electrodes cannot be used.

PROPERTIES OF ELECTRIC CURRENTS

Before a more detailed description of diathermy apparatus is given a few technical terms that are commonly used will be defined.

A direct current (abbreviated D. C.) consists of a flow of electrical charges through a conductor in one direction only. Such a current is delivered from a battery or a direct current generator (fig. 1 A).

An alternating current (abbreviated A. C.) consists of a flow of electrical charges through a conductor in such a manner that the electrical charges oscillate back and forth in the electrical circuit. The number of oscillations (cycles) per second is called the frequency. This type of current is usually supplied for illumination and for electrical power devices. It is the type of current generated by the vacuum tube diathermy machine. Essentially, the vacuum tube diathermy machine changes sixty cycle alternating current, which causes electrical stimulation, to fifty million cycle current, which does not stimulate (fig. 1 B).

The spark gap diathermy machine delivers damped alternating current. The current through the patient oscillates back and forth, each oscillation becoming smaller and smaller, until the current ceases. After a brief pause the whole process is repeated. The decrease in amplitude of each oscillation is called damping (fig. 1 C).

The force that drives electrical charges through a circuit is the electromotive force and is measured in volts. The electric current, which measures the number of charges flowing through a circuit per second, is measured in amperes. The ratio of volts divided by amperes is the electrical resistance and is measured in ohms. It is a measure of the resistance encountered by the flowing electrical charges. A physiologic analogy would be the action of the heart, in which the driving force would be the mean aortic pressure, the current the minute volume of the heart and the resistance that of the arterioles, capillaries and venules.

The voltage that drives the alternating current under goes a cyclic variation from a high positive value through zero to a high negative value. The highest value reached is the peak voltage. The effective voltage continually exerted, however, is not the peak voltage, just as the systolic pressure is not the effective pressure of the blood flow. The effective driving voltage is called the effective voltage or "root mean square" voltage and would correspond to the mean aortic pressure in the analogous blood flow. The analogy must not be carried too far, since the alternating current voltage is both positive and negative while aortic pressure, although it fluctuates, is always positive.

An electrical condenser consists of two metallic plates, which are good conductors of electricity, separated by a medium called the dielectric. The circuit of figure 2 represents a condenser in an electrical circuit containing a meter that measures current when it flows and a battery that can supply a direct current. When the connections are made a current will flow for a very short interval of time until electrical charges accumulate on the plates of the condenser. Once the charge has accumulated, the flow of current will cease. If the battery is replaced by an oscillator or a generator of alternating current,

Fig. 3—Construction of vacuum thermocouple used to measure high frequency currents and effective voltages

A current will oscillate back and forth in the circuit. Electrical charges will flow into the condenser and then out again as the current reverses. This back and forth movement of the electrical charges into and out of the condenser forms the electric current. A condenser possesses capacity, which is measured in farads or microfarads. The larger the area of the condenser plates and the closer they are together, the greater will be the capacity. The capacity depends on the mechan-

Fig 4—A thermionic vacuum tube B rectifier vacuum tube

ical dimensions of the condenser. A condenser will block the flow of direct current but will permit the flow of alternating current. A condenser used in this way is called a "blocking condenser."

A coil of wire wound in the form of a helix possesses inductance, which is measured in henrys or millihenrys. The value of the inductance depends on the number of turns and the coil diameter. A large inductance coil offers a considerable impedance to the flow of alternating current. A large coil in an alternating current circuit would reduce the current without an appreciable loss of energy. "Choke coils" are coils with a large inductance, i. e., many turns and a large diameter, which prevent the passage of alternating current but permit the passage of direct current.

HIGH FREQUENCY APPARATUS

The High Frequency Ammeter or Milliammeter—These instruments are now made of the thermocouple type, although the older machines have hot wire meters. A vacuum thermocouple consists of an evacuated glass bulb (fig 3) with four wires. Two of these conduct the high frequency current to a small heated wire. This wire is heated by the high frequency current, the greater the current, the more heat produced and the higher the temperature of the wire. A thermocouple junction of two dissimilar metals soldered or brazed together is joined to the center of the heating wire, the junction of the two metals being at the point of contact with the heated wire. The junction of the dissimilar metals behaves as a small direct current battery which produces a voltage proportional to the temperature or the squared value of the current. This voltage is recorded on a small galvanometer to which the other two wires from the evacuated bulb are attached.

The conventional diathermy ammeter is usually placed on the panel of the diathermy machine and indicates the amount of high frequency current flowing through the patient. Since the diathermy dosage is regulated by the meter, this instrument must be kept in good order. If the needle does not indicate zero when the switch is "off," the needle should be adjusted to zero by a small regulating screw near the bearing of the needle. The metallic parts of one electrode cable

should not touch the metallic parts of the other cable. This would cause a short circuit, which might "burn out" the small heated wire of the vacuum thermocouple or the fuse in the meter. If the needle of the meter does not deflect promptly in a normal manner when the current is turned "on," it should be examined by a qualified person. It is relevant to mention at this point that meters on short wave machines do not read the true value of the current passing through the patient.

Low Frequency Transformer—Every diathermy machine, whether vacuum tube or spark gap, contains a low frequency transformer. This changes low voltage to high voltage. The transformer consists of an iron core on which two separate coils are wound, the coils being called the primary and the secondary. The ordinary sixty cycle illuminating current flows through the primary.

The Thermionic Vacuum Tube—This is an evacuated tube resembling a light bulb. It is made of glass with an insulated base. Metallic connections pass through the base from the outside to the inside of the tube (fig 4 A). These metallic connections on the outside are made to fit into metallic sockets through which electric current can be conducted into the interior of the tube. The metallic parts within the tube consist of the following: 1. A filament heated by a suitable current. When heated, the filament emits electrons. 2. An anode, which is usually a large plate of metal or carbon. This plate is connected to a source of positive electricity, which attracts the negative electrons emitted by the filament. 3. Between the anode and the filament there may be interposed one or more grids. These grids, which consist of wire screens, are usually connected to varying voltages, so that when the grid voltage is changed the electric current flowing from filament to plate changes in a corresponding manner.

The rectifier vacuum tube (fig 4 B) is a thermionic vacuum tube containing a heated filament which emits electrons and an anode to which the electrons are drawn. The current flows only in one direction through this tube, namely, negative

Fig 5—Diagram of a typical spark gap diathermy machine. A variable inductance in primary circuit of input transformer to regulate current. T 60 cycle transformer. S spark gaps. C condensers in oscillating circuit. L inductance of oscillating circuit. O Oudin coil. A high frequency ammeter.

charges (electrons) from the filament to the anode. If this tube is placed in a circuit in which an alternating voltage is applied, the current will flow only in one direction and will not oscillate, as would happen if the tube were not in the circuit. This tube is used to

change alternating current to direct current. It is used in vacuum tube diathermy and to rectify the current for x-ray machines.

The Spark Gap Diathermy Machine—Figure 5 shows the circuit of the spark gap diathermy machine. The 60 cycle alternating current from the power mains passes through the primary of the 60 cycle transformer, *T*. The amount of current flowing through the primary

Fig 6—Representative types of diathermy currents. A cutting current slow damping wave trains from 0.00001 to 0.000015 second apart. B coagulation current wave train. C diathermy current wave train wave trains 0.0001 second apart rapid damping.

can be regulated by the variable inductance, *K*. The secondary coil of *T* delivers high voltage alternating current to the condensers, *CC*. These store electrical charges. When a high charge accumulates, the condensers "discharge" and a current oscillates back and forth in the circuit *SCCL*. The frequency of oscillation depends on the amount of inductance *L* and the capacity *C*, the lower the capacity and inductance, the higher the frequency. The type of current is the damped oscillating type already described. The part of the oscillating current of the circuit *SCCL* passes to the patient through the meter.

The Vacuum Tube Diathermy Machine—This machine is simply a vacuum tube oscillator. The machine converts the 60 cycle alternating current from the power mains into high frequency current with frequencies varying from 10 million to 100 million cycles per second. Detailed descriptions of such oscillators for therapeutic purposes are quite infrequent in the medical literature. Two of the more recent descriptions are those of Schereschewsky² and Bishop.³ Figure 7 shows a typical vacuum tube generator of high frequency currents of the type used by Bishop. The circuit is not recommended by the Council over any other practical hookup. Two transformers, *T*₁ and *T*₂, convert the 110 volt sixty cycle alternating current from the power mains into (1) low voltage current to heat the filaments of the vacuum tubes (transformer *T*₁) and (2) a high voltage current for the anodes of the vacuum tubes (transformer *T*₂). The high voltage current from *T*₂ is rectified, i. e., converted into direct current in the rectifier vacuum tubes 866. The high voltage direct current is applied to the anode of the

oscillator tubes 852. The oscillating circuit in which the high frequency current is generated contains the inductance *L* and the capacity *C*. The frequency of the alternating current is determined by the magnitudes of *L* and *C*. To produce the current of very high frequency, *L* and *C* must be small. *Ch Ch* are "choke coils," which prevent the high frequency current from flowing into the rectifier tubes and the transformers. *C*₂ *C*₂ are two "blocking condensers," which prevent the direct current from the anode of the oscillating tubes from flowing into the high frequency circuit and the grids.

The theory of the production of an alternating current will not be given here, since it involves a considerable amount of technical discussion and mathematics. The theory in a brief form is well presented in an article by Rechou⁴ and in more detail by Morecroft.⁵

REQUIREMENTS OF A DIATHERMY MACHINE

Energy Requirement—A diathermy machine for clinical use must be able to deliver sufficient energy to the patient to produce the required amount of heat in the tissues. A machine should be capable of delivering to the patient 200 watts of high frequency power.⁶

Efficiency Requirement—Diathermy machines will overheat if poorly constructed or if made of inferior

Fig 7—One type of vacuum tube generator of high frequency currents.

material. The heat is produced in the machine and not in the patient. This is particularly noticeable in the transformers. Many manufacturers of diathermy machines are guilty of furnishing their machines with cheap and inefficient transformers. During a test of the diathermy machine the temperature of the trans-

former must be noted. This must not exceed the limits specified by the American Institute of Electrical Engineers.

Frequency Requirement—The high frequency diathermy current must not cause electrical stimulation of the tissues. In order to prevent electrical shock, the frequency should be high. It is recommended that the frequency exceed one-half million cycles per second.

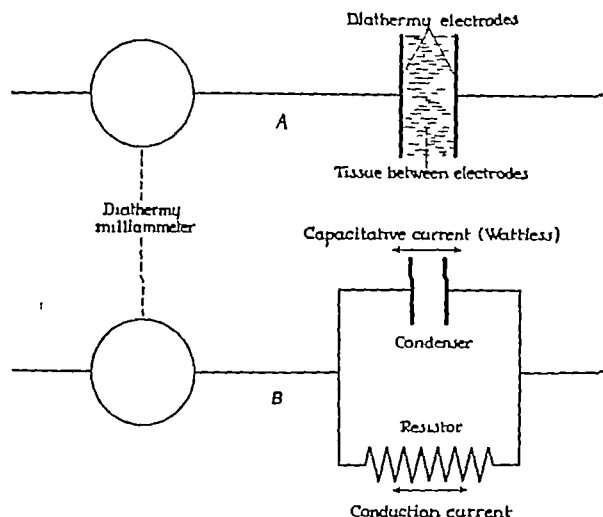

Fig 8—Tissue between diathermy electrodes represented electrically

There should be no low frequency transient currents associated with the high frequency currents.

Insulation and Protection Requirement—The cables to the patient and the connections to the cables should be well insulated with no exposed metallic parts raised to a high voltage. The insulation within the machine must be adequate to prevent internal leak currents, which would lower the efficiency. The spark gaps must be covered.

Testing of Machines—The Council on Physical Therapy has been conducting a series of rigid tests on various commercial diathermy machines. Any machine approved by the Council will conform to the specifications required.

THEORY OF THE HEATING OF TISSUES BY HIGH FREQUENCY CURRENTS

1 Diathermy—In a diathermy treatment, metallic or saline pad electrodes are applied to the skin of the patient. The diathermy current passes through the tissues and warms those tissues traversed by the current. The current follows the tissues of lowest electrical resistance, such as blood and muscle, and evades when possible the tissues of high resistance, as fat and bone. In cases in which a high resistant tissue cannot be avoided, as subcutaneous fat directly beneath the electrodes, the heating is more intense, as is indicated by Joule's law, the heating being proportional to the resistance multiplied by the squared value of the current. Hence a high resistance and a high current value would produce a high temperature. The tissue between diathermy electrodes can be represented electrically by the arrangement in figure 8. The tissue between the electrodes behaves as a dielectric and the metallic plates as the plates of a condenser; hence it is necessary to consider two types of current: (1) that which flows to charge and discharge the condenser plates and forms the wattless component, and (2) the conduction current, which flows through the tissue and

produces heat. It has been shown⁷ that the diathermy current for diathermy frequencies less than 2×10^6 cycles per second is almost entirely conduction current. The significance of this is that the diathermy current as indicated by the diathermy meter is all utilized in heating the patient. More technical details are given in an earlier paper.⁸

The upper limit that may be used without causing burns and possible necrosis lies between 10 and 20 milliamperes per square centimeter or 100 milliamperes per square inch of the smallest electrode.

The specific resistances in ohms of human tissue for high frequency currents are as follows:⁹ skin, 289, fat, 2,180, bone, 1,800, muscle, 110, kidney, 126, liver, 298, cardiac muscle, 132, spleen, 256.

Since the diathermy current is almost entirely conduction current, that is, the tissues offer a pure resistance to the diathermy current with no reactance, it is possible to obtain the heat production in the tissue. If a high frequency voltmeter is connected in parallel with the patient and the effective voltage and current read from the voltmeter and ammeter, the rate of heat production in the patient is equal to the voltage multiplied by the current (watts).

2 Short Wave Diathermy—Pätzold¹⁰ has shown that an electrolytic conductor such as an electrolytic solution placed between the metallic electrodes but not in actual contact with the electrodes can be represented by the equivalent circuit shown in figure 9. It is reasonable to suppose that the same circuit would represent a section of the human body between similar electrodes, though it should be remembered that the human body is a complex, heterogeneous structure. The condenser C_1 represents a condenser in parallel with the tissue to be heated. Part of the high frequency current charges and discharges the metallic plates and does not pass as a conduction (heating) current through the patient. This component I_1 of the total current I is said to be wattless. Hence the ammeter does not measure the true heating current, since some of the energy is radiated into space. The condensers C_2 , C_2 have each a dielectric of air between two conductors, namely, the

Fig 9—Equivalent circuit representing an electrolytic solution placed between metallic electrodes but not in actual contact with the electrodes.

tissue and one metallic plate. This capacity becomes lower the closer the metallic electrodes approach the tissue in which event the conduction current flowing

through the tissue is increased at the expense of the wattless current, I_1 . The true capacity of the tissue C depends on the dielectric constant and the shape and size of the body between the electrodes. R depends on the specific resistance of the tissues. For the human body between metallic electrodes the values C_1 , C_2 , R and C are unknown. They vary with the shape, size, position and composition of the tissues.

The closer the body between the electrodes is brought to the electrodes, the more the short wave treatment approaches the conditions of diathermy. That is, the closer the body to the electrodes the greater will be the surface heating of the tissue next to the electrode. In order to have a more nearly uniform heating throughout, the tissues would have to be at a considerable distance from the electrodes.

It has been shown by Hosmer,¹¹ Patzold,¹⁰ McClenan and Burton,¹² and others that there is a selective heating of the electrolytic conductor, which depends on the frequency of the alternating current and the specific resistance and dielectric constant of the tissue. Thus, as the frequency is varied the various tissues in turn would be selectively heated, the ability to be selectively heated depending on conductivity and dielectric constant. Theoretically, at least, there is a possibility that a certain tissue could be selectively heated by varying the frequency of the machine. This has been demonstrated for dead tissues by McClenan and Burton^{12b} and by Jellinek.¹³ Schliephake¹⁴ has shown that a temperature distribution in parts of dead cadavers heated by short wave diathermy differs from the temperature distribution of diathermy. These experiments, while of theoretical interest, do not apply without modification to the living animal. The circulation of the blood and its variations in the different tissues and under different conditions affect markedly the temperature of a heated organ. For clinical use, temperature distributions in living animals or human subjects must be made. Recently Sheard and Pratt¹⁵ have measured temperature distributions in the region of the knee joint of anesthetized dogs when heated with short wave diathermy of a frequency of 27 million cycles per second. They have found in agreement with others that electrodes placed close to the skin give a temperature distribution in the tissues resembling the usual diathermy.

The usual spark gap diathermy furnishing alternating current of frequencies from one half million to two million cycles per second heats those tissues with the lower electrical resistance, such as blood, muscle and glandular tissue. These are the tissues which possess a rich blood supply. With the conventional type of diathermy there is little possibility of overheating these tissues, since the rapid flow of blood through them distributes the heat to neighboring parts. With short wave diathermy the conditions are somewhat different. The short wave diathermy tends to produce selective heating of tissues, which depends on their electrical resistance, dielectric constant and structure. The temperature to which a tissue is raised during a treatment

depends on two factors namely, (1) the rate of heat production by the electrical current, raising the temperature, and (2) the rate of blood flow through the tissue, which lowers the temperature. In the case of articular cartilage, for instance, where the blood supply is poor, there is a possibility of overheating. The seriousness of this is enhanced when one considers the slow rate of regeneration of this cartilage.

CONCLUSION

The newer method of heat therapy, namely, the short wave diathermy, is at present in an experimental stage. Much valuable research has been done to clarify the problems involved, at the same time there are in the literature some very confusing and misleading statements in regard to the merits of this form of therapy. For a good critical discussion we would recommend the recent article by Mortimer and Osborne.¹ In particular, we would recommend that, owing to the lack of knowledge on many phases of this work and the indications of dangerous possibilities, the newer machines be used with the utmost caution. On the other hand, conventional diathermy is an old established form of therapy about which much is known that has proved to be of definite clinical value.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

BISMUTH SUBSALICYLATE (See New and Nonofficial Remedies, 1935, p 123)

The following dosage form has been accepted

Amponle Bismuth Subsalsicylate with Butyn D R L 1 cc A 10 per cent suspension of bismuth subsalsicylate-U S P in peanut oil to which has been added 0.4 per cent of butyn and metapnen 1 20 000. Each cubic centimeter represents from 0.057 to 0.059 Gm of elemental bismuth.

Prepared by the Abbott Laboratories North Chicago Ill No U S patent or trademark

DIOTHANE (See New and Nonofficial Remedies, 1935, p 54, also THE JOURNAL, Feb 23, 1935, p 641)

The following dosage form has been accepted

Ampules Diothane 0.5% in Solution of Sodium Chloride 0.6% 6 cc

"SHADOCOL NOT ACCEPTABLE FOR N N R" A CORRECTION

THE JOURNAL, March 16, 1935, page 922, contains the Council's report explaining the unacceptability of Shadocol (Davies, Rose & Co., Ltd.) for inclusion in New and Nonofficial Remedies. In this report appears the following statement:

'The addition of lactose and citric acid represents an unnecessary modification which is probably useless except as a commonplace flavor. It is fallacious to consider a modification of this sort as representing 'an original product' the result of extensive research,' and to claim that it is unequaled by other preparations.'

A letter received from Davies, Rose & Co., Ltd., explains to the Council that the citric acid was added not as a flavor but for the purpose of liberating the acid form of tetraodophenolphthalein from the sodium salt as a fine precipitate, with a view to the obviating of gastric irritation. Accordingly, the criticism expressed in the quoted statement becomes invalid. The Council regrets the error in its original report and deems it necessary that this statement be published. However, the product remains unacceptable because of the proprietary name.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORTS

RAYMOND HERTWIG, Secretary

ACCEPTANCE WITHDRAWN BIOVEGETIN

Manufacturer—BioVegetin Products, Inc., Chicago

Description—Finely powdered mixture of dehydrated spinach, tomatoes, carrots and irradiated yeast

Manufacture—Fresh spinach freed of roots and stems is mechanically washed and placed on cloths on wire trays which are run through tunnels of warm filtered air not exceeding 71 C. The dry spinach is pulverized and stored in drums. Fresh carrots are mechanically washed, peeled, again washed and subsequently treated as the spinach. Tomatoes, trimmed by hand and washed, are processed as described above. Irradiated yeast (not less than 2,500 U S P vitamin units per gram) is autoclaved for twenty minutes at 17 pounds pressure to kill the yeast. The powdered ingredients are mixed in definite proportions, sifted, and packed in jars.

| Analysis (submitted by manufacturer) — | per cent |
|--|----------|
| Moisture | 10.3 |
| Ash | 6.1 |
| Fat (ether extract) | 3.4 |
| Protein (N X 6.25) | 20.1 |
| Reducing sugars as invert sugar | 13.2 |
| Sucrose (copper reduction method) | 6.4 |
| Starch | 2.5 |
| Crude fiber | 6.5 |
| Carbohydrates other than crude fiber (by difference) | 53.6 |
| Iron (Fe) | 0.013 |
| Calcium (Ca) | 0.51 |
| Copper (Cu) | 0.0012 |

Calories—3.3 per gram, 94 per ounce

Vitamins—Assay shows 400 U S P vitamin D units per gram

Reason for Withdrawal of Acceptance—BioVegetin was formally accepted Sept. 22, 1933. Recently it was learned the BioVegetin Products, Inc., was merchandising a product named VegeMucene in conflict with the policies of the American Medical Association as set forth in the rules of the Council on Pharmacy and Chemistry. VegeMucene is an unoriginal preparation of powdered okra marketed under a noninformative and misleading proprietary name, promoted with exaggerated and unwarranted therapeutic claims and advertised directly to the public, for which reasons the product is unacceptable to the Council on Pharmacy and Chemistry (THE JOURNAL, Jan. 26, 1935). Since the merchandising practices of the manufacturing company, here cited conflict with the policies of the American Medical Association the acceptance of BioVegetin is being withdrawn in accordance with the recently adopted Committee rule that

No food product or class of food products or advertising therefor will be accepted or if accepted will be retained if in the opinion of the Committee such acceptance is likely to be construed as an acceptance or approval of any other products or activities of a firm when such other products or activities of such firm are in conflict with the policies of the American Medical Association as set forth in the rules of the Committee on Foods or those of the Council on Pharmacy and Chemistry or the Council on Physical Therapy.

ACCEPTANCE WITHDRAWN LUCKY GLUTEN FLOUR

Manufacturer—Federal Mill, Inc., Lockport, N. Y.

Description—Wheat gluten flour containing not more than 44 per cent of starch.

Manufacture and Analysis—See THE JOURNAL, July 15, 1933, page 211.

Uselessness as a Special Purpose Food—Lucky Gluten Flour, manufactured specially for use in diets restricted in dextrose formers, was accepted in 1933 before the Committee adopted definite requirements for a special purpose flour of this character. To be eligible for acceptance at this time such type of flour shall contain dextrose formers yielding dextrose in an amount not greater than 3.3 Gm. per hundred cubic centimeters (the dextrose equivalence being computed as the carbohydrate,

plus 58 per cent of the protein, plus 10 per cent of the fat content of the food). Dextrose formers of Lucky Gluten Flour, on the other hand, yield approximately 50 Gm. of dextrose per hundred cubic centimeters.

There is authoritative evidence that commercially prepared special diabetic foods such as gluten flour are of limited usefulness to the diabetic patient and that the availability of insulin makes them no longer necessary. Artificial substitutes for ordinary foods are not to be favored; it is much better for the diabetic patient to learn how to plan his diet with foods in common use and readily available. The diet should be exactly prescribed in carbohydrate, protein and fat, and total calories.

The designation of a food as a "diabetic food" merely because it is low in carbohydrates is now unwarranted and misleading and gives the erroneous impression either that the food taken in unrestricted quantities in diabetes is harmless or that it has remedial action. Except for the necessity of restricting foods to avoid overstepping the food tolerance, there are no special diabetic nutrition requirements. The exploitation of starch-free or low carbohydrate foods containing an excess of protein for use by diabetic patients is unwarranted. Protein may be tolerated almost as poorly, if not quite as poorly, as starch in diabetes.

Because Lucky Gluten Flour is adjudged without usefulness or special adaptability for inclusion in diets restricted in dextrose formers, it no longer will be listed among the accepted foods of the Committee on Foods.

Gluten flours of other manufacturers, for the reasons stated, are not eligible for acceptance.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

SOLITAIRE BRAND SIEVED ASPARAGUS, BEETS, CARROTS, GREEN BEANS, PEAS, PRUNES, SPINACH, TOMATOES UNSEASONED

Distributor—The Morey Mercantile Company, Denver

Packer—The Nielsen Corp., Ltd., Oakland, Calif.

Description—Sieved asparagus, beets, carrots, green beans, peas, prunes, spinach and tomatoes, prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt. These products are the same as the accepted Warranty vegetables and fruits (THE JOURNAL, April 27, 1935, p. 1504, April 13, 1935, p. 1331, March 16, 1935, p. 923, April 6, 1935, p. 1241, April 20, 1935, p. 1419, March 30, 1935, p. 1074, Feb. 2, 1935, p. 399, June 1, 1935, p. 1999).

REYNOLDS' BRAND PITTED RED CHERRIES, WATER PACK

REYNOLDS' CHERRYLAND BRAND PITTED RED CHERRIES, WATER PACK

Manufacturer—Reynolds Preserving Company, Sturgeon Bay, Wis.

Description—Canned cooked red Wisconsin cherries packed in water without added sugar or salt. The same as Cellu Red Pitted Cherries Packed in Water Without Added Sugar or Salt (THE JOURNAL, Sept. 14, 1935, p. 885).

SWEET LIFE EVAPORATED MILK

Distributor—The Sweet Life Food Corporation, Brooklyn.

Packer—Oatman Condensed Milk Co., Dundee, Ill.

Description—Canned unsweetened evaporated milk, the same as Oatman's Brand Evaporated Milk (THE JOURNAL, April 16, 1932, p. 1376).

Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, NOVEMBER 2, 1935

CONTROL OF RABIES

Bites by domestic animals, particularly dogs, are not as uncommon today as might be believed. A recent statistical survey¹ contains the rather surprising statement that in New York City alone there was a total of 20,416 instances of bites by animals reported to the department of health during 1934 and that 19,443 of these were inflicted by dogs. Laboratory examinations of specimens of the available biting dogs showed that forty-four were rabid. The survey further shows that there has been a steady increase in the number of reported instances of dog bites in New York since 1908 and that, despite the availability of satisfactory anti-rabic vaccines, the number of deaths from human rabies has remained virtually unaltered for the past twenty-five years both in New York City and in the country at large. There were sixty-five fatal cases of human rabies in the registration area of the United States in 1933. In view of these data it is obvious that increased attention should be directed to minimizing biting by dogs and thus to the occurrence of rabies.

The control of rabies is often a difficult and unsatisfactory procedure. Reliance cannot be placed solely on the treatment of the exposed subject by the Pasteur prophylactic method, since this treatment, even though properly given, may not be given sufficiently early and does not invariably protect the patient. The logical procedure is the minimizing of canine rabies and its spread by biting dogs. Actual immunization of dogs against canine rabies has been extensively studied in recent years but should be regarded as still in the experimental stage, though there is some indication that it may prove effective. The effective control of rabies at present, therefore, must revert to the control of all biting dogs. This plan necessarily involves not only the dog but also its owner. There should be a thorough elimination of all stray and unlicensed dogs. Those which are licensed should not be permitted to roam freely on public grounds but should be restrained by

a leash or should be muzzled. Statistical studies in New York have shown that bites from dogs on a leash or muzzled, as required by law in that city, are extremely rare. Apparently there has been laxity on the part of the law-enforcing personnel in New York or a lack of cooperation on the part of dog owners to prevent the complete effectiveness of the dog restraining devices. The suggestion has been made¹ that the cooperation of dog owners in the enforcement of this law might be more completely elicited if the responsibility of dog bites and the burden of all the accruing expenses should be placed squarely on the owners of the dogs.

As a supplementary measure to legislation, the general enlightenment of prospective dog owners as to the type of dog most suitable to his use and facilities might be of value. It is well known, for example, that female dogs are gentler with children than are males, that German police dogs bite more frequently than do other breeds, and that long-haired dogs develop rabies less frequently than short-haired dogs because of the greater opportunity for the removal of infectious saliva by the coat of the former. All dog owners should be advised to seek information regularly from a capable veterinarian regarding the diet, training and current health problems of their dogs.

ISOTOPES IN PHYSIOLOGIC RESEARCH

The term isotopes was coined by Soddy to describe two or more chemical elements of different atomic weights but with identical chemical properties. For the most part, these isotopic elements are also physically identical, except only with regard to the relatively few physical properties that depend on atomic mass directly. The development of knowledge of isotopes represents much of interest not only to the chemist and the physicist but to the investigators in all branches of science. About 253 stable isotopes are known,¹ and only a few elements remain without definite data to confirm the existence of all elements in isotopic forms. It is now clear, for example, that chlorine consists of two isotopes of atomic weight 35 and 37, mixed in such proportions as to give the usual atomic weight of 35.46. Some elements may have six isotopes (krypton), while other elements contain even more (xenon and tin).

Probably the most interesting chapter in the story of isotopes is the discovery of deuterium, the heavy isotope of hydrogen.² While this isotope of mass 2 exists only in small proportion, about 1 in 5,000 to 6,000 of the main isotope of mass 1 nevertheless, because of the marked difference in mass of the two components, the relative concentration of the two isotopes can be altered very definitely by various physical

and chemical processes. This has resulted in the preparation of water in which the isotope of mass 1 is completely replaced by the isotope of hydrogen of mass 2. Although this heavy water resembles ordinary water in appearance, its physical and chemical properties in general show definite differences. The surface tension is lower, while the viscosity is much greater. The density of this heavy water is about 10 per cent greater than ordinary water, while its freezing point is 3.8 degrees C higher and its boiling point is elevated 1.42 degrees C. The preparation of the new water has resulted not only in the detailed study of its chemical and physical properties but also in investigations of its effect on the processes occurring in animal and plant life. A large number of reports have been published dealing with the influence of heavy water on growth, on enzyme reactions, and on fundamental transformations in the cell. It appears, in general, that the substitution of heavy hydrogen for its lighter isotope in ordinary water produces a fluid which retards the majority of biologic processes.

It is hardly necessary to point out the wide and important fields of work opened up by the discovery of heavy hydrogen. Heavy water has received much attention, but it is obvious that the research is not limited to this solvent. Because of the greater mass of deuterium as compared to ordinary hydrogen, it is to be expected that compounds formed with the new isotope should in some cases exhibit rather different properties from the normal hydrogen compounds. Preliminary inorganic and organic chemical studies have verified this postulation. More interesting from the physiologic standpoint has been the recent suggestion² that deuterium might be used as an indicator in the study of intermediary metabolism. The fact that the hydrogen isotope deuterium occurs in the same proportion in the hydrogen of organic matter as it does in the hydrogen of ordinary water seems to indicate that the living organism is incapable of distinguishing between the organic molecules which contain deuterium and those which do not. If the reverse were true, organic matter of different biologic organs would display differences in isotopic ratios. Investigators at Columbia University have reported³ interesting applications of this fact. The following compounds containing heavy hydrogen have been prepared: stearic acid containing 4 deuterium atoms, a deuterium-containing fat and a sterol derivative with 2 deuterium atoms in the compound. These new products are reported to have properties indistinguishable from those of their naturally occurring analogues. Nevertheless, as the deuterium content of these substances or their metabolically produced derivatives can readily be determined from the properties of the water formed on combustion, their fate in the organism can be followed even after considerable dilution.

Interesting results already obtained from the use of deuterium as an experimental tool support the belief that much of value may be expected from investigations of this type. Mice have been fed a diet in which was incorporated the deuterium-containing fat, and after a time the tissues of the animals were subjected to analysis for deuterium. Although the diet fed was insufficient in quantity to maintain the body weight of the animals, it was found that a large amount of the absorbed fat was deposited in the depots, thus indicating that the fat which was burned was not oxidized directly after absorption but had been taken from the fat depots. Dietary fat is therefore for the most part apparently deposited in the fat tissues before it is utilized. These authors have also made suggestive and important preliminary observations of sterol metabolism which indicate that certain interesting relationships between the members and the derivatives of this lipid group may be clarified by the use of deuterium in metabolism studies.

CYANIDE ANTIDOTES AND MEDICAL PROGRESS

Recent successes with methylene blue and sodium nitrite in the treatment of cyanide poisoning are striking.¹ As a result, the treatment of poisoning in general is receiving more attention and undergoing creditable revision. These tendencies are resulting in more than the development of life-saving measures. They are leading to a fuller appreciation of fundamentals in pharmacologic reactions and physiologic processes. Sometimes the relationships are quite unsuspected.

Methylene blue and sodium nitrite are far apart chemically, physically and pharmacologically, so that a common factor in their antagonism of cyanide poisoning would hardly be suspected. Yet that is exactly what has been discovered, and the discovery testifies to the value of the experimental method in medical science. This common denominator is specific and definite. Its utilization should remove all guesswork from the treatment of cases of cyanide poisoning.

Historically, however, the discovery is one of those curious anomalies of reportorial service in medicine. For nearly forty years the potential value of the common denominator in cyanide poisoning, the methemoglobin process, slumbered unnoticed in the tomes of medical science. For twelve years the demonstrated value of methylene blue in cyanide poisoning also went unrecognized until the pharmacologist Hug, in South America, successfully reasoned to this conclusion. After all, twelve or forty years is but a brief period in the history of human endeavor. Today the merely interesting experiment of yesterday is a life-saving measure. The world-wide confirmations of this discovery, beginning with Hungary and then spreading to

Belgium, Sweden, the United States and South America, testify to the truly international scope and spirit of medical science

Eventually J C Geiger, health official of San Francisco, acting on the recommendation of Hanzlik and Richardson,¹ demonstrated the humanitarian value of this comparatively old, yet recent, discovery.² This single clinical experiment has deservedly earned a widespread approbation. In one sweep it confirmed the value of controlled experimental procedure, saved human life, and marked progress in medical science. These striking events have moved so suddenly that their full significance for medicine cannot be measured yet. But it is already apparent that many investigations of oxidation-reduction dyes, of methemoglobin agents and processes, and of related problems have been stimulated the world over. Apparently, nothing need be too remote or unsuspected to illuminate the dim crossings and by-ways on the great highway of medical progress.

Current Comment

TROPICAL DISEASES IN THE UNITED STATES

The field of tropical medicine has been enormously extended in recent years by the introduction or discovery of certain diseases in temperate climates. With the more recent discoveries, tropical medicine has come to require a knowledge of many of the sciences: protozoology, helminthology, entomology, bacteriology, meteorology, mycology, in addition to the various clinical fields of medicine, furthermore, the subject is not limited to these sciences as applied to man but extends to lower animals as well. Therefore the physician who practices tropical medicine may have to use knowledge from many other fields of learning. Not only are tropical diseases of paramount importance to public health, but the etiology and prevention of some of them are still a challenge to science. Realizing the need for more information on the distribution and incidence of tropical diseases, an advisory committee of the Division of Medical Sciences of the National Research Council made a survey¹ based on public health reports and information gathered from all parts of the world in reply to a questionnaire. In this geography of disease is a section reporting the information obtained from the latest available published health reports of fifteen states in the United States. Among the diseases usually classified as tropical diseases reported in one or more of these states are amebic dysentery, malaria, hookworm disease, relapsing fever, ascariasis, plague, leprosy, beriberi, bacillary dysentery, typhoid and dengue fever. Malaria was reported in thirteen of the fifteen states, hookworm disease and bacillary dysentery in ten states, ascariasis in eight states, amebic dysentery in four, leprosy in four, relapsing fever and plague

in at least one state, and dengue fever in five states. In this group of states the greatest number of cases of malaria was reported in Mississippi, with 36,133 cases for the year 1932, next in order was Georgia with 3,411 cases in the same year, and Louisiana with 3,214 cases in 1933. Typhoid is still widespread, in some of the fifteen states in this group several hundred cases were reported. Oklahoma heads the list with 2,620 cases of typhoid in 1931, and Georgia is next with 1,799 cases in 1932. The state reporting the largest number of persons infested with hookworm disease was Alabama with 16,380 positive stools reported among those examined in 1932, and Florida is second on the list with 13,750 positives in 1933. These figures, however, are no indication of the number of clinical cases of hookworm in these two states, as they represent only the positive observation of hookworm eggs in stools examined during the periods specified. Mississippi in 1932 led the list in cases of bacillary dysentery, reporting 5,688 cases, and Georgia was second with 435 cases. Leprosy was reported in California, Florida, Georgia and Louisiana. Much additional information on tropical diseases in these states is presented in the survey, as well as similar data for numerous other countries throughout the world. The director of the studies, Dr E B McKinley, and the advisory committee, comprising Drs Frederick P Gay, Richard P Strong and the late Theobald Smith, point out that their report is far from complete and is only a preliminary study, resulting from two and a half years of work. However, it serves as a beginning of a much needed larger study, which may in the future provide data in a field that is constantly growing in importance.

AMERICAN RED CROSS PLAN AND HIGHWAY FATALITIES

Because of the alarming total of road accidents in the United States each year, the American Red Cross has determined to establish highway first aid stations throughout the country. In 1934, 36,000 persons were killed on the highways and 1,255,000 were injured. With immediate first aid, many of these lives might have been saved. Already 100 stations are in operation and within the next few weeks 400 or more additional stations are to be established. In each of these stations there will be a list of the nearest local physicians and hospitals, developed by the local chapter of the Red Cross on consultation with the local medical society. The workers and attendants at the first aid stations have been instructed by the Red Cross to receive their training and supervision from local physicians. The attendants must, of course, have completed the standard course in Red Cross first aid. In these first aid stations there will be available, in addition to the personnel, first aid kits, splints for fractures, ready reference telephone directory of medical, hospital and ambulance service, and other first aid equipment. It is understood, of course, that this first aid service is not meant to take the place in any way of medical care. No recompense is to be received by those giving first aid, nor may any donations be received in this connection.

THIS PANEL SCHEME

EDWARD F. KLEIN, M.D.
PERTH AMBOY, N. J.

I'll look no more Let my brain turn and the deficient sight
topple down headlong—King Lear act 3 scene 6

The only excuse for writing this article on the panel system is one self conceived and self assumed. However, for justification I feel that my experiences and contacts in Germany, Austria, France and Great Britain afford me some right to communicate to my colleagues facts which they have the right to know. In some instances I have drawn on personal talks with physicians working under the panel scheme in their respective countries, in others, on knowledge gained through experience in clinics, in hospitals and with physicians not under the scheme. Many statements are excerpts of panel laws and are consequently true to the crude facts.

Of particular concern is the panel system in England. Being late in introducing compulsory national health insurance, England had the advantage of experiences with other countries. Fundamentally, the medical problems of national health insurance, though varying in detail from country to country, are the same. In the early part of the present year the magazine *Today* (the mouthpiece of the national administration) editorially advocated some such scheme as at present in use in England.

It is well known that private work is scarce, physicians agree as to the drastic reduction of fees, of increasing competition from hospitals, cheap clinics, unorthodox medical practitioners, various new cults instituted, the increasing number of new graduates and finally that there is actually a desperate economizing in medical treatment generally on the part of the public. "We may resentfully chafe at our bonds, and like Prometheus vainly strive to wrest ourselves from the rock of the past in our eagerness to bring relief to the suffering children of men." We must, however, be increasingly conscious of the fundamental fact that it is the past that makes the present, and that what goes before is the key to what comes after.

The good health of the people being of supreme national importance, it is not surprising that governments have sought to compel their working population to take part in some form of health insurance. Germany introduced national health insurance in 1883, Austria in 1885, Hungary in 1891 and Great Britain in 1911 the system becoming operative in 1912. The National Health Insurance Act in general reads as follows: All employed persons (now numbering in Great Britain about 18,500,000), are required to take part in a scheme of state insurance for health purposes. The scheme applies, with certain exceptions to all persons employed by way of manual labor and to all other employed persons whose rate of remuneration is not more than £250 (about \$1,250) a year.

The employer and employed person pay weekly contributions. The state adds a grant out of the public exchequer and the insured person becomes entitled to certain benefits, the principal being medical benefit, periodic cash payments during sickness and disablement known as sickness and disablement benefits and maternity benefit, i.e. a lump sum payment on the birth of a child. The scope of medical benefit consists in the provision of medical attendance by a general practitioner only, proper and sufficient medicine, a limited number of medical and surgical appliances and the furnishing of records of illness and a certificate of incapacity by the physician. It does not include attendance or treatment in respect of confinement.

In April 1930 the British Medical Association brought forward proposals for a general medical service for the nation which would include about 90 per cent of the population. In

1931 a deputation from the National Federation of Professional Workers, representing 400,000 workers, was received by the secretary to the Ministry of Health, asking coverage for all employees earning up to \$2,500 a year. The demand for the extension of health insurance has also brought in its trail the demand for cheaper services by specialists. Many societies have secret lists of specialists available to insured patients at special reduced fees. May 12, 1935, I saw this article in the *London Express*.

PUBLIC HEALTH INSURANCE FOR THE MIDDLE CLASS FAMILY

Health Insurance for the Middle classes who are not covered by the State has been introduced by a group of Lloyds underwriters who are operating on a national scale. For the middle class man it solves the problem of doctors' bills, nursery home fees (private rooms in private hospital) and also offers maternity benefit of £12 [\$60] if a doctor is employed and £8 [\$40] otherwise. For husband, wife and two children the premium is 15 shillings [\$3.75] a month. By paying a higher premium the insured may obtain higher rate of benefit. As age increases, the amount of premium rises. On the other hand if no claim is made in a year there is a reduction of 25 per cent in the next year's premium. Anybody can join the scheme without passing a medical examination.

THE SET-UP OF THE PANEL SYSTEM

(Assume now that the English panel system was to be adopted in its entirety.)

Every qualified medical practitioner is entitled to treat insured persons. In the main the conduct of the physician will be governed by a county insurance committee consisting of from twenty to forty members, one fifth of whom are physicians, three fifths represent insured persons, and one fifth are appointed by the county council appointing druggists and women members. This committee is responsible for the maintenance of adequate medical service for insured persons. In addition to the insurance committee in each county there is set up a local medical committee, representatives of all physicians in the area, and a panel committee, representatives of insurance physicians who are under agreement to treat the insured patients. The function of the local committee is to preserve the interest of the profession as a whole.

Any insured person may apply to a physician for acceptance and inclusion on the physician's list. The physician is entitled to refuse to accept the applicant on his list. If he decides to accept him, he will sign the applicant's medical card and send it to the insurance committee within seven days. The committee will note it and return it to the insured person. The record cards sent by the committee from time to time constitute the physician's list of insured persons for whom he is responsible. Included in the physician's list of responsibilities are those also who are (1) assigned to him by the insurance committee, (2) applicants not on any other physician's list whom he does not wish to accept on his list, and (3) applicants who are on the list of another physician who is not available.

REMOVAL OF INSURED PERSONS FROM THE LIST

Any insured person may be removed from a physician's list as a result of action by (1) the physician after fourteen days' notice, (2) the insured person by transfer to another physician, and (3) the insurance committee.

THE NUMBER ON THE PHYSICIAN'S PANEL

In 1933 the average number of panel patients for the average physician was 961. A maximum number of 2,500 insured persons is fixed and no physician single handed may ordinarily have more. In special individual cases the amount may be extended to 3,000 and conversely a lower limit of 2,500 may be allowed when desirable. If a physician employs one or more assistants he may obtain an additional 1,500 for each assistant. When two or more physicians are in partnership, the average of all partners must not exceed 2,500. A physician is not only personally responsible for providing adequate medical treatment to his insured patients but is also normally required to give

actual treatment himself. In certain cases, however, another physician may treat one's patients on one's behalf but one is responsible for all acts and omissions of the deputy or assistant and any agreement that one makes with a deputy or partner cannot override the terms of one's agreement with the insurance committee and one must notify the committee in advance whenever one proposes to be away from one's practice for more than a week, also to inform the committee of any arrangements one has made with another physician to treat one's patients when one is unable. The patient, however, is entitled to the physician's personal services except when the physician is prevented by some reasonable cause. A partnership must be in fact as well as in name. One partner is entitled to not less than one third of the share of the pay of any other partner. In 1933 the average number of panel physicians in England was 19,250.

REMUNERATION

Payment for medical services must be looked for to the insurance fund to which the insured person has paid to cover the full cost of medical attendance. A central fund is constituted and is based on an estimate by a government actuary of the whole insured population. This fund is distributed between several areas and the local fund between the physicians. The method of distributing the local fund is one to be determined by the wishes of the majority of the insurance physicians in each area, through their panel committee. Although the central fund or pool is determined on a capitation basis, the local distribution may be on a capitation basis or on the basis of payment per case with such modification as may find favor in the locality. Distribution on a capitation basis is actually the method everywhere in operation. Generally one's share of the fund is calculated by the number of patients on one's list—called units of credit multiplied by the present agreed capitation fee of 9 shillings (\$2.25) a year.

If the average number of units of credit or panel patients on the physician's list is 961, his income will be broadly \$2,162.25. The settlement is quarterly. The insurance committee at the end of the year will give the physician a statement showing the method by which his share has been calculated. His amount is further calculated with an addition or deduction, as the case may require, for emergency treatment rendered by him to another physician's patients or by other physicians to one's own patients.

RANGE AND TYPE OF MEDICAL SERVICE

The following type services have been held to be within the insurance contract for which one receives no additional fee:

- 1 Arrest of hemorrhage from the gums
- 2 Extraction of a tooth under an anesthetic
- 3 Tapping of hydrocele
- 4 Removal of a cyst in the neighborhood of the knee
- 5 Removal of a fibro-adenoma of the breast.
- 6 Operation for cellulitis
- 7 Removal of a needle from the foot
- 8 Amputation as a cure for hammer toe
- 9 Taking blood for a Wassermann test
- 10 Treatment of fracture of both bones of the leg with dislocation
- 11 Treatment of gonorrhea
- 12 Curettement of the uterus
- 13 Operation for fissure in ano, operation for deep abscess of the neck
- 14 Dislocation of the elbow and reduction under chloroform
- 15 Removal of epithelioma of the lip

Regarding preventive treatment, if the physician considers it necessary or desirable that this should be done, he is by virtue of his agreement under obligation to do it and cannot charge or accept a fee for doing it. If a patient refuses to undergo an operation and the refusal may result in need for more frequent attendance, the physician is requested to provide the attendance free of charge.

TREATMENT BY SPECIALISTS

The insured person is not entitled to receive specialist treatment as part of his medical benefit. However, if the physician is of the opinion that the patient's condition requires treatment which is not within the scope of the physician's terms of service, the physician must advise the patient as to the steps that should be taken in order to obtain such treatment. Where possible, the clinics and hospitals or the use of consultants associated with the insurance societies should be used. Whenever one performs an operation or gives treatment which is, in one's opinion, a specialist service, one is required to notify the insurance committee on a special form within two days after the date on which the treatment is given. Consultation with specialists is not affected by provisions of insurance acts and as a rule one may make no special charge. Regarding specialist services rendered by oneself, the burden of proof will be on the physician to show both the operation or service called for skill beyond that possessed by general practitioners as a whole and that one is possessed of the requisite skill and experience. Only in this manner is one entitled to a specialist fee.

VISITS

When the insured patient's condition requires, it is the physician's duty to visit and treat him at any place where he may be at the time, if that place is within the district in which one has undertaken to visit the insured persons. The rules adopted by the insurance committee require an insured person needing a visit to give the physician notice before a specified hour of the day on which the visit is required, except in cases of emergency. A further rule to protect the physician from unreasonable night calls is that which says that the insured person shall not summon the physician to visit him between the hours of —p m and —a m except in emergency. The actual time adopted by the insurance committee appears in the rules printed on the insured person's medical card. The physician is required to visit those patients whose condition requires it and not merely those who send the physician notice.

PENALTIES

For neglecting the treatment of a patient, fines ranging from \$5 to \$500 may result, and even removal from the panel. In addition, further penalties may result for charging fees to insured persons, for failure to keep records, and for failure to comply with the practitioner's obligations toward the regional medical officer. The committee within whose power these actions lie for adjudication is known as the advisory committee consisting of a chief medical officer of health or his deputy, two other medical officers of the ministry, and three physicians chosen by the minister from a panel nominated by the Insurance Act Committee. The duties of the regional medical officer will be outlined further in the paper.

PRESCRIBING AND SUPPLYING DRUGS

The panel druggist or chemist receives a list of authorized appliances and drugs. Standards for dressings have been adopted, a national formulary has been issued. The main intent is to provide therapeutic efficiency with regard to economy. For example, liniments are to be ordered in quantities of 2 ounces, ointments in 1 ounce quantities, gauze as 1 square yard. As far as possible, practitioners should keep a check on the consumption of medicine. If the cost of a physician's prescribing is called into question, any formal inquiry—which must precede any imposition of a penalty—will be conducted by a purely medical body, the panel committee.

ISSUE OF CERTIFICATE OF INCAPACITY

Sickness benefit and disablement benefit under national health insurance acts are weekly cash payments to the insured person while he is rendered incapable of work by some specific disease or by bodily or mental disablement. The physician's certificate

is the evidence of incapacity on which payment is ordinarily made to one's patients. Every certificate is in effect a check drawn on the benefit funds of approved societies and even the slightest laxity in the issue of a certificate may produce serious financial result. The obligation that the physician has accepted is to issue medical certificates to one's insured patients free of charge. There are seven authorized types of certificates used in the course of insurance practice.

REGIONAL MEDICAL OFFICERS

Regional medical officers (R M O) are officers of the Ministry of Health. They are referees in disputes concerning disabilities and examine records that physicians are required to keep. Consultations regarding capacity or incapacity for work falls under the scope. Such consultation may be demanded either by an insurance society or by the physician. It is the duty of the physician to produce records of attendance on their insured patients to the regional medical officer or his representative at all reasonable times and to furnish him any necessary information in regard to any entry. The regional medical officer is entitled to visit the physician's office or other places where the records are kept but must first give due notice of his visit. The total amount annually distributed in sickness and disablement benefits in Great Britain, mainly on evidence of insurance physician certificates for 1934, was over \$100,000,000.

Failure to observe rules causes irregularities in certification, and failures are viewed with grave concern. It may result in disciplinary action, such as removal from the panel or the withholding of part of a physician's remuneration. Such irregularities as antedating and postdating certificates, signing of blank forms, certifying that the patient was examined on a given date when in fact there has been no such examination, the patient not having been seen, are heavily penalized.

In 1921 there were 69,543 cases referred to the regional medical officers for settlement of disputes arising from sickness and disability claims. In 1925 there were 204,088 and in 1931 there were 644,332. From 1931 to 1934, benefit overpayments were the subject of report in twenty-three out of every hundred accounts certified, and it is to be borne in mind that the physicians are responsible for the certifications.

RECORDS OF ILLNESS

The physician is required to keep and furnish records in the official forms of the illness of his patients and his treatment and to afford the regional medical officer access to one's records at all reasonable times. The physician is required to record such facts as he considers would be of use to himself in any subsequent treatment of the patient or to any other practitioner into whose care the patient may subsequently pass.

COMPLAINTS

1 Any insured person or member of the family or other representative of a deceased person may raise a question to the subcommittee of the Insurance Committee in respect to the treatment rendered by a physician or of any alleged failure on his part to render treatment or of some other breach of his duties under his term of service.

2 A physician may raise a question as to the conduct of an insured person while receiving treatment.

3 An approved society may raise a question as to the actions of a physician in regard to any certificate that he is required to furnish to a member of the society.

4 After considering the subcommittee report, the insurance committee may take the following actions:

- (a) Penalize the physician financially by a deduction from his remuneration.
- (b) Diminish the number of insured persons that the physician may treat.

- (c) Withhold medical benefit sums payable to the physician.
- (d) Remove the physician from the panel after

- (1) Grave or persistent failure to provide treatment.
- (2) Personal misconduct of such a character as to bring the service into disrepute.
- (3) Repeated breaches of conditions of service without a definite guaranty against recurrence.

As regards insured persons on a physician's list, one is not permitted to demand or accept any payment for any treatment falling within one's term of service. The position is in no way affected by a desire or request on the part of the insured to receive treatment as a private patient. The acceptance of a fee from an insured person not on one's list who specifically asks for treatment as a private patient does not constitute a breach of one's term of service. But it is usually to be deprecated. It may cause a physician considerable inconvenience if the patient afterward denies that he made such a request and applies for a refund of his money.

MISCELLANEOUS NOTES OF CONCERN TO PANEL PHYSICIANS

In case of the death of a physician, patients may be free to procure another. Owing to the absence or mental or bodily disability of a physician, the insurance committee may notify his patients that he is not in a position to carry out his obligations, and arrangements are made with another physician to carry out the practice. Special reduction and modification is arranged by the committee when a physician refuses to make night calls or refuses to have patients assigned to him or has a limited list.

COMMENT

We in the United States simply plead for the continuation of sane, simple medical economics. We hope that our past contentions will not be exploited as ridiculous or absurd or antiquated. Obviously if any conclusions can be drawn from my remarks it is that panel medicine is medicine in a hurry, it is medicine by fear and threats, by bookkeeping, by penalties, by regulations and by starvation wages. Bernard Shaw said "A hungry doctor is perhaps more dangerous than a wild beast."

Dr. Dain, chairman of the Insurance Acts Committee of the British Medical Association, said in his foreword to the third edition of the Medical Insurance Practice, "It must to many have seemed amazing that so everyday a matter as the doctoring of a person could have produced or required such a mass of regulation." Do masses of regulation go hand in hand and concomitant with the good health of our people?

The main object of the insurance act is to enforce the health of the working part of the community, and by its results in this direction the act must be judged. If it has not improved the public health or has not improved its relation to its cost then the act has failed in its most important object.

C. W. Armstrong, in 'The Survival of the Unfittest' says, 'All states upon which a premium is set tend to become more common. If sickness and unemployment receive as premium a free gift of other people's money, these states will therefore tend to spread. As long as a man has to rely on healthy living for health, good workmanship for employment, and thrift for a rainy day, healthy living, good workmanship and thrift will be encouraged and become more common and they bring material reward, but as soon as material reward is to be gained with less effort in neglecting health, work and thrift, such negligence tends to increase.'

In 1930 Dr. Alfred Cox, late secretary of the British Medical Association, in a paper contributed at the Congress of the Royal Sanitary Institute, said "My correspondents nearly all agree that the insurance system combined with other forms of social assistance has had a bad effect on the morale of the working class. They regard public funds as inexhaustible."

WHAT OF PANEL MEDICINE IN OTHER COUNTRIES?

In Germany there was a tendency to limit the professional rights of the physician. There was a movement to extend the income limit of those entitled to insurance and at the same time to limit the total amount which any physician could receive out of the funds. In Austria the condition was very grave. The insured patients were frequently better off than the physicians. In France I was told that the physicians had succeeded on paper, at any rate, in getting adopted its cardinal points, among which were free choice of physician and payment to the physician direct by the patient on a tariff (scale). In Hungary I found a dispute. The profession itself was divided into one group which wished for free choice of physician and those physicians already employed, who opposed it. For all practical purposes, the physicians on the panel system were officials paid by fixed salaries, which were very low.

The position of the physicians in Yugoslavia was that there existed an excess of physicians, and their position was serious. In Holland there is no compulsory insurance and the profession is content.

Dr Cox again further said: "If the medical profession, so recently much less complex than today, and much less complex than it will be tomorrow, is to practice the art of medicine usefully and sanely, it is necessary that the practitioner should conserve his liberty, his free will and that he should have constantly in view only the interest of his patient with no fear that his diagnosis, his prognosis and above all his treatment will be governed by any other consideration."

The Association professionnelle des medecines has always emphasized that, if the profession reacts against the efforts made to socialize it, it is in the conviction that medicine made impersonal, bureaucratized and loaded up with clerical obligations is not social progress either for physicians or for their patients.

Has the panel system improved the death rate in England? In the sickness benefits from 1921 to 1927, claims of men have risen 41 per cent, claims of unmarried women 60 per cent and claims of married women 106 per cent. In the claims for disablement benefit (payment after twenty-six weeks of sickness benefit) the claims of men have risen 85 per cent, claims of unmarried women 98 per cent and claims of married women 159 per cent.

In 1920, 1928 and 1934 respectively the number of insured persons was 12,787,000, 13,798,000 and 18,500,000. The money paid out in sickness and disablement benefits amounted to £6,708,000 (\$33,540,000), £14,689,000 (\$73,445,000) and £20,131,930 (\$100,659,650). This does not include medical benefits, which in 1934 in England alone amounted to \$45,311,995, maternal benefits, hospitalization and dental or optical treatment. The cost of drugs consumed per person has risen from 55 cents to 80 cents in 1927. Since 1927 the cost of medicine and appliances has increased by more than another half million pounds (\$2,500,000). In 1921 the total cost of drugs was £1,189,450 (\$5,947,250). In 1927 it was £1,886,874 (\$9,334,370).

CONCLUSIONS

The evidence is conclusive that despite the payment of extraordinary sums, compulsory health insurance is an absolute failure to reduce the amount of sickness of workers.

Where are all these schemes leading to? What are the prospects for those entering the profession in large numbers today? Where are the potential possibilities for future discoveries? What then is panel medicine? It is medical terrorism. It is medicine blank and void of hope and endeavor.

Sir George Newman, former chief medical officer in the Ministry of Health, in the Sir Charles Hastings Lecture 1928, said: "The organization of health, which is the organization of life, is the primary, though not the supreme business of the government, and as I humbly see it, the supreme business of the

government is to assist and to cultivate the health heritage of every reputable physician in every age. There should be no crossing of the medical bar, but hand in hand, the government should go forward with the doctors 'upon the prow of the ship of civilization' in the bitter battle against disease."

136 Market Street.

Association News

**ANNUAL CONFERENCE OF SECRETARIES
OF CONSTITUENT STATE MEDICAL
ASSOCIATIONS AND EDITORS
OF STATE MEDICAL
JOURNALS**

The Annual Conference of Secretaries of Constituent State Medical Associations and Editors of State Medical Journals will be held in Chicago November 15 and 16. The first session will be convened at 10 a. m. Friday, November 15, and all meetings will be at the Palmer House.

Officers of state medical associations and county medical societies who wish to attend this conference will be heartily welcome as will individual members of the Association who may desire to be present.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Trachoma Among the Indians—Dr. Polk Richards, medical director of trachoma activities for the Indian Service, conducted a trachoma institute at Fort Apache, October 4-11, for all physicians and nurses in the U. S. Indian Service doing trachoma work. Dr. Phillips Thygeson, assistant professor of ophthalmology, State University of Iowa College of Medicine, Iowa City, was the guest speaker. The service maintains a special school at Fort Apache for children with trachoma. There is an eighteen bed hospital for acute cases and operative work in connection with the school, in which there are 275 pupils.

ARKANSAS

Meeting of Urologists—The Southwestern branch of the American Urological Association will meet at Little Rock, November 15-16. Speakers will include:

Dr. Henry McClure Young, Columbia, Mo., The Best Surgical Approach to the Kidney.
Dr. Robert H. Akin, Oklahoma City, Transverse Urethral Bridging Following Prostatic Resection.
Dr. Samuel K. Broyles, Amarillo, Texas, Alkaline Incrustation of the Bladder.
Dr. Bransford Lewis, St. Louis, Nephropexy and Its Critics.
Dr. Julius Frischer, Kansas City, Mo., Preventive Measures in Urinary Calculus Formation.

CALIFORNIA

Society News—At a meeting of the Alameda County Medical Society, Oakland, October 21, Drs. Dexter N. Richards and Olin H. Garrison, Oakland, spoke on "Intestinal Obstruction" and "Metabolic Diseases and Their Relation to Teeth," respectively. Dr. Stanley H. Mentzer, San Francisco, discussed differential diagnosis of diseases of the gallbladder before the Solano County Medical Society, October 8, in Vallejo. At a meeting of the Trudeau Society of Los Angeles, October 22, a symposium on pneumothorax treatment was presented by Drs. John Q. A. Scroggy, Carl R. Howson, John W. Nevius and John R. Neal. Dr. Robert Sonnenschein, Chicago, addressed the Los Angeles Society of Ophthalmology and Otolaryngology, October 28, on reflexes or referred signs and symptoms of diseases of the nose, throat and ear. At a meeting of the Los Angeles Surgical Society, October 18, Dr. Max M. Peet, Ann Arbor, Mich., spoke on "Surgical Treatment of Hypertension."—A joint meeting of the staff of Mills Memo-

rial Hospital, San Mateo, and the San Mateo County Medical Society was addressed, October 9, by Karl F. Meyer, Ph.D., San Francisco, on undulant fever.—Dr. Loyd Thompson spoke on "The Modern Renaissance of Syphilis" before the San Diego County Medical Society, October 8.

GEORGIA

University News—The new Milton Antony contagious disease clinic of University Hospital and the University of Georgia Medical School was to be formally opened, October 1.

Dental Inspection of School Children—About 16,000 school children in Fulton County will be inspected by members of the Fifth District Dental Association in a program of dental health recently begun by the association. In a similar project in the county last year in which 8,568 children were examined, the incidence of defective teeth was found to be 82.6 per cent, representing an average of 27 cavities per child, it was stated. The state and county health departments are cooperating in the project.

Society News—Speakers before the Seventh District Medical Society at Chickamauga, recently, included Drs. John M. McGhee, Cedartown, on "Gonorrhea in the Male," and Henry L. Sams, Dalton, "Hygiene and Management of Pregnancy."—Dr. Herbert C. Schenck, Atlanta, among others, addressed the Eighth District Medical Society in Valdosta, October 8, on "Indications for Lung Collapse Measures in Tuberculosis, with Special Reference to Technique and Management in Artificial Pneumothorax."—At a meeting of the Second District Medical Society in Thomasville, October 11, Drs. James H. Pound, Chattahoochee, Fla., among others spoke on "Surgery in the Mentally Ill" and Henry M. Moore, Thomasville, "Tobacco Amblyopia."—The Georgia Medical Society was addressed in Savannah, October 8, by Dr. Robert L. Oliver on "Metaplasia in the Breast," and Dr. Julian F. Chisholm Jr. presented a case report on "Tumor of the Optic Nerve."—Dr. Quinney A. Mulkey, Millen, addressed the Burke-Screven-Jenkins Counties Medical Society at Millen, October 3, among others, on "Treatment of Injuries to the Eye."

ILLINOIS

Personal—Dr. Carl A. Peterson, Moline, has been named a district superintendent of health on the staff of the state health department, effective October 1. Moline will be his headquarters.—Dr. Harry A. Yeager has recently been appointed health officer of Litchfield.

Society News—Dr. Harold B. Cushing, Montreal, Canada, among others, addressed the quarterly meeting of the Iowa and Illinois Central District Medical Association in Moline, October 18, on "Newer Phases of Prophylactic Inoculation in Children—Pertussis, Measles, Diphtheria, Poliomyelitis and Scarlet Fever."—Dr. Charles F. Read, Elgin, among other speakers, discussed psychoanalysis before the Kane County Medical Society at a meeting, October 9, at the Elgin State Hospital.

Typhoid Traced to Contaminated Milk—An outbreak of typhoid occurred at Grand Tower, Jackson County, during August, one month after a family reunion at which twelve persons were present, seven of the persons who attended the dinner were ill. The hostess recalled that she had bought from a dairy four quarts of raw milk from which she had made the ice cream. Milk from the dairy in question had gone to each household of thirteen other persons involved in a similar outbreak in the same community, with onset during July and August. The health department points out that while the investigation failed to identify definitely the source of contamination, evidence indicated that the milk was responsible. It is believed that a typhoid carrier or unrecognized case among the dairy help or customers was the original source. A young girl whose parents lived on the farm came home ill from Washington late in July. She had fever and was found to have typhoid when she entered a St. Louis hospital later for treatment of appendicitis.

Chicago

Society News—Dr. David J. Davis, dean University of Illinois School of Medicine, will deliver the presidential address before the Institute of Medicine of Chicago, December 3, on "Some Studies on the Epidemiology of Streptococcus Infections."

Dr. Pemberton Will Give Mayo Lecture—Dr. John DeJ. Pemberton, associate professor of surgery, University of Minnesota Graduate School of Medicine, Rochester, will present the annual Mayo lecture of Northwestern University at Thorne Hall, November 15. Dr. Pemberton's subject will be "Development of Thyroid Surgery."

Lectures at University of Illinois—Dr. Alfred Adler, Vienna and New York, will lecture at the University of Illinois College of Medicine, November 4, on "Medical Psychology." Rear Admiral John Downes, commandant of the ninth naval district, Great Lakes, Ill., will deliver the Memorial Lecture at the university, November 11. The lecture has been endowed by alumni and faculty members of the school in memory of the alumni and members of the staff of the medical school who died during the World War.

Lectures on Psychoanalysis—Dr. Franz G. Alexander opened a series of introductory lectures on psychoanalysis at the Institute for Psychoanalysis, October 24. The lectures are presented every Thursday afternoon. Subjects include historical development of the main concepts of psychoanalysis, concept of the unconscious, fundamentals of psychic dynamics (repression, regression, fixation, reaction-formation, sublimation), theory of instincts, development of the personality, general concepts of the structure of neuroses and psychoses, principles of the psychoanalytic technique, and application of psychoanalysis to other sciences.

INDIANA

State Medical Election—Dr. Edmund D. Clark, Indianapolis, was chosen president-elect of the Indiana State Medical Association at its recent annual meeting in Gary. Dr. Roscoe L. Sensenich, South Bend, took office as president, succeeding Dr. Walter J. Leach, New Albany, who died just before the meeting. Memorial services were held for Dr. Leach during the meeting. Dr. Clark will take office Jan. 1, 1937. The next annual session will be held in South Bend. Dr. Clark graduated from Bellevue Hospital Medical College, New York, in 1891. He was director of base hospital number 32 during the World War and in 1931 was president of the Indianapolis Medical Society. At present he is secretary of the University of Indiana School of Medicine, Indianapolis, and professor of surgery.

IOWA

Society News—At a meeting of the Iowa Clinical Surgical Society in Sioux City, September 28, clinics were conducted by Drs. Robert Q. Rowse and Prince E. Sawyer, general surgery, Archibald F. O'Donoghue, orthopedic surgery, and Lawrence E. Pierson, urologic surgery.—Speakers before the Dubuque County Medical Society in Dubuque, September 24, included Dr. Max Cutler, Chicago, on "Diagnosis and Treatment of Breast Tumors."

Immunization in Polk County—State and local health authorities, parent-teacher associations and other agencies are cooperating in a campaign to immunize children in Polk County against diphtheria. It has been decided to devote one month each year to this campaign. This year it will begin in November. The campaign will be publicized by radio, newspapers and speeches. The Des Moines Council of Parent-Teachers Associations will do much of the educational work in the personal contact with parents.

Meeting of Ophthalmologists—The Iowa Academy of Ophthalmology and Otolaryngology will hold its annual meeting in Council Bluffs, November 7, with the following speakers:

Dr. Frank W. Dean, Council Bluffs, Causes of Phorias
Dr. Jack V. Treynor, Council Bluffs, Laryngotracheitis
Dr. John F. Stageman, Council Bluffs, Asthmatic Bronchitis
Dr. Wayland H. Maloy, Shenandoah, Tuberculosis of the Cornea and Iris
Dr. Earl C. Montgomery, Atlantic, Serous Meningitis as a Complication of Acute Mastoiditis
Dr. Lloyd G. Howard, Council Bluffs, Head Specialists
Dr. Abbott M. Dean, Council Bluffs, Intraocular Steel
Dr. Sydney D. Maiden, Council Bluffs, Practical Management of Antrum Infection

KENTUCKY

Advisory Committees on Social Security—The governor has appointed an advisory commission on social security, with Dr. Arthur T. McCormack, secretary, Kentucky State Medical Association as chairman. Dr. McCormack named several subcommittees to deal with the various titles of the Social Security Act. In addition, he has asked the committee on public relations of the state medical association to act as the committee on public health. The council of the state association and the committee on medical economics have been asked to serve as advisory members of the section of the commission dealing with all matters pertaining to health.

MAINE

Personal—Dr. James A. Spalding, Portland, has retired as editor of the *Maine Medical Journal* and Dr. Edwin W. Gehring, Portland, has been named to succeed him.

MARYLAND

Personal—Dr Henry E Sigerist, professor of the history of medicine, Johns Hopkins University School of Medicine, Baltimore, received an honorary degree from the College of Physicians of Madrid during the recent International Congress of the History of Medicine.—Dr Robert E Garrett, superintendent of the Spring Grove State Hospital, Catonsville, since 1928, has resigned, effective November 1, on account of ill health. Dr Garrett has been connected with the institution for thirty-five years.

State Appointments for Health Survey—William Thurber Fales, Sc D, director of the bureau of vital statistics, Baltimore City Health Department, has been designated state supervisor for Maryland in the national health survey being conducted by the U S Public Health Service. Wilmer H Schulze, Phar D, director of the bureau of environmental hygiene, is serving as industrial hygiene specialist for the industrial survey of the records of sick benefit associations to determine sickness and death rates according to occupation. This material is intended to supplement the data gathered in the house-to-house canvass.

Causes of Death in 1934—Accounting for 22 per cent of all deaths in Maryland in 1934, heart disease led the list of causes of death for the year. The mortality rates per hundred thousand of population for white persons and Negroes, respectively, were 264.9 and 265.8. Second in the causes of death was nephritis, with a rate of 127.5 per cent for white persons and 180.5 for Negroes. Cancer, all forms, was third, with a rate of 126.3 for white persons and 88.7 for Negroes. Tuberculosis, which was responsible for the greatest mortality from 1901 through 1917, stood seventh in the list of causes for 1934, having for the first time on record a death rate lower than that for accidents, which was sixth.

MASSACHUSETTS

Extension Lectures—The Massachusetts State Medical Society has begun its series of graduate extension courses in various centers throughout the state. Different centers have been selected for the spring series. Consideration will be given to diseases of the lung, liver, kidney and bladder, cancer, arthritis, dermatology, ophthalmology and otolaryngology, pediatrics, immunology, latest developments in endocrinology, and syphilis and gonorrhea.

Mental Hygiene for Adults—A university extension course on 'keeping mentally fit' will begin, November 5, under the auspices of the Massachusetts Department of Education and the Massachusetts Society for Mental Hygiene. Sessions will be held at the Gardner Auditorium, State House, Boston, and lectures will be presented by the following:

Joseph Jastrow, Ph D, New York, 'Keeping Mentally Fit', November 5.
Dr Bronson Crothers, assistant professor of pediatrics, Harvard Medical School, 'Management of Disease in Childhood in Relation to Mental Health', November 12.

Dr Lawson G Lowrey, formerly director, Institute for Child Guidance, New York, 'The Child and the Modern World', November 19.

Dr Donald Gregg, president, Massachusetts Society for Mental Hygiene, 'How Psychiatry Can Aid in Meeting Problems of Modern Life', December 3.

Dr James J Walsh, professor of physiologic psychology, Cathedral College, 'Current Ethical Trends', December 10.

Dr Karl M Bowman, assistant professor of psychiatry, Harvard Medical School, 'Adult Problems', "The Blues and Fatigue States", December 17.

Dr Jacob Kasanin, clinical director, state hospital for mental diseases, 'Howard R I Psychoanalysis and Mental Health', January 7.

Dr Albert Warren Stearns, dean, Tufts College Medical School, 'Adults in Difficulty', January 14.

Society News—Dr Charles S Burwell, Boston, will address the Suffolk District Medical Society and the New England Heart Association at the Boston Medical Library, December 11, on "Constrictive Disease of the Pericardium".—At the annual meeting of the Massachusetts Psychiatric Society, October 29, George Sarton, Sc D, associate of the Carnegie Institution of Washington, D C, gave an address on "Genius, with Special Reference to Science and Music".—Dr Harry B Levine, among others, addressed the New England Heart Association in Boston, October 28, on "Pulmonary Infarction Complicating Severe Chronic Mitral Valve Disease with Failure".—Speakers before the Worcester District Medical Society in Rutland, October 9, were Drs David Zacks Brookline on "X-Ray Diagnosis of Silicosis versus Tuberculosis," and Gullu Lindh Muller, Rutland, "Value of Blood Studies in the Selection of Cases for Thoracoplasty".—Dr Robert A Kilduffe, Atlantic City, N J, discussed 'Highlights in the History of Hospitals' before the Springfield Medical Society, October 28.—Dr Leland S McKittrick, Boston, addressed the New England Physical Therapy Society, Boston, October 16, on "Treatment of Hemorrhoids".

MICHIGAN

Board of Embalmers—Members of the State Board of Embalmers and Funeral Directors, created by an act of the last legislature, have been appointed by Dr Clyde C. Slemmons, Lansing, state health commissioner. The board will work in conjunction with the state department of health.

Dr Wessinger Honored—Dr John A Wessinger, health officer of Ann Arbor since 1909, has been made a life member of the Washtenaw County Medical Society. A similar honor was conferred on Dr Wessinger by the Michigan State Medical Society during its annual meeting in Sault Ste. Marie, September 27. Both honors were in recognition of his many years as a practicing physician. Dr Wessinger is 75 years of age and a graduate of Detroit Medical College, class of 1882.

Society News—The Kalamazoo Academy of Medicine was addressed in Kalamazoo, October 22, by Drs Raymond W Waggoner, Ann Arbor, on "The Paroxysmal Disorders", Richard M McKean, Detroit, "Disturbances in Thyroid Function", Harley A Sears, Kalamazoo, "Endocrine Therapy in Schizophrenia," and Roy A Morter, Kalamazoo, "The Problem of Mental Disorders".—A symposium on anesthesia will be presented before the Wayne County Medical Society, November 4, by Drs Myra E Babcock and Francis J Murphy, Detroit. Dr Rosco G Leland, director, Bureau of Economics, American Medical Association, Chicago, discussed "The Economics of Modern Medicine" before the society, October 21.—The Detroit Society of Neurology and Psychiatry held its first annual meeting at Ann Arbor, September 19, speakers included Dr Konstantin Lowenberg, Ann Arbor, on "Cerebral Changes in Nitrous Oxide Deaths".—The house of delegates of the Michigan State Medical Society adopted a resolution during the recent annual meeting establishing a section on radiology.

MISSOURI

Society News—Dr Thomas FitzHugh Jr, Philadelphia, discussed "Recent Advances in Clinical Hematology" before the Kansas City Academy of Medicine, October 18.—Speakers before the second annual meeting of the Missouri Academy of Science in Kansas City, October 24-26, included Dr Buford G Hamilton on "What Maternal Welfare Hopes to Accomplish in the State of Missouri".

Medical-Dental Service Bureau—Offices for the new Medical-Dental Service Bureau have been established in St. Louis at 317 Missouri Building. Mr Ross Garrett, director of a similar bureau in Washington, D C, is in charge of the organization. Representatives have been chosen from the three societies participating in the plan to make up a board of directors for the St. Louis Medical Society. Drs Fred W Bailey, David P Barr, Howard M Foster, Curtis H Lohr, John C Morfit, James Archer O'Reilly, Major G Seelig, Carl F Vohs, Thomas C Wimber and William O Winter, for the St. Louis County Medical Society. Dr Elmer O Breckenridge, for the St. Louis Dental Society. Drs Otto W Brandhorst, Val H Frederick, Virgil Loeb, Edward L Mayer, Ronald H Miller and Rudolph C Seibert.

NEW JERSEY

Health at Trenton—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended October 19, indicate that the highest mortality rate (17.6) appears for Trenton and that the rate for the group of cities as a whole was 11. The mortality rate for Trenton for the corresponding week of last year was 14.6 and that for the group of cities, 10.9. The annual rate for the eighty-six cities for the forty-two weeks of 1935 was 11.4, as against a rate of 11.3 for the corresponding period of 1934. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

NEW YORK

Hospital News—Two new buildings were dedicated at the Suffolk Sanatorium, Holtsville, October 23. One is for children, has a capacity of sixty and is named for the late Dr Joseph H Marshall, first president of the board of managers of the hospital. The other building, which has fifty-four beds, is for the care of acute cases, it is named for Dr William H Ross, Brentwood, first president of the county board of health.

Dr Greenburg Appointed Director of Industrial Hygiene—Dr Leonard Greenburg, health officer of New Haven, Conn, has been appointed executive director of the division of industrial hygiene of the state department of labor,

effective October 15 Dr Greenburg, who is a native of New York, received a degree in sanitary engineering from Columbia University in 1915, the doctorate in public health from Yale University, New Haven, in 1923 and his medical degree from Yale in 1930. He has served as an officer of various sections of the National Safety Council dealing with industrial hazards, as a member of a committee to investigate sanitary conditions at Ellis Island and as a member of a committee studying cerebral meningitis and sanitary conditions on shipboard and in the Orient in 1931. He is associate clinical professor of public health at Yale University School of Medicine. He will begin immediately a study of silicosis and other dust disease hazards in industry in connection with the new workmen's compensation law.

New York City

Afternoon Lectures at the Academy—The tenth series of Friday afternoon lectures at the New York Academy of Medicine will begin November 8 with a talk by Dr Milton Benjamin Rosenbluth on "Newer Drug Therapy." Lecturers for the remainder of the year will be

Dr Thomas T. Mackie, "Diagnosis and Treatment of Intestinal Infections"

Dr Emanuel Libman, "Points in Medical Diagnosis"

Dr William P. Healy, "Significance of Uterine Bleeding in Later Life"

Dr George Draper, "Significance of the Human Constitution in Clinical Medicine"

Dr Ralph Pemberton, "Philadelphia: Present Status of Arthritis and the Treatment of It"

Dr Erdmann Honored—A new auditorium at the New York Post-Graduate Medical School and Hospital has been named in honor of Dr John F. Erdmann, who was professor of surgery in the school and director of the surgical service for more than twenty years. At a dedication ceremony, October 21, speakers included Drs. Walter G. Lough, Walter T. Dannreuther, Raymond B. Allen, William B. Talbot, Charles Gordon Heyd and Arthur F. Chace. Dr Charles J. Imperatori, who is chairman of the faculty association, presided and Dr Chace accepted the Erdmann Auditorium, which is a gift from the board of directors, the faculty association and the professional staff of the hospital in recognition of Dr Erdmann's long services to the institution. Dr Erdmann spoke briefly in acknowledgment. A bronze bust of Dr Erdmann, the gift of the faculty association, also was installed.

Dr Emerson Awarded Medal—The American Public Health Association at its annual meeting in Milwaukee, October 7, awarded the William Thompson Sedgwick Medal for distinguished service in public health to Dr Haven Emerson, president of the association in 1933-1934. Dr Emerson has been since 1922 professor of public health administration and director of the institute of public health at Columbia University College of Physicians and Surgeons, from which he was graduated in 1899. At various times he has served as professor of hygiene and preventive medicine at Cornell University Medical College, health commissioner of New York City and medical adviser and assistant director of the bureau of war risk insurance in the U. S. Treasury Department. In 1929 he made a survey of health and sanitation in Athens, Greece for the health section of the League of Nations and has made similar surveys for many cities in this country. He served in the medical corps of the army during the World War and received the Distinguished Service Medal.

OHIO

University News—The International Health Division of the Rockefeller Foundation has granted to the school of applied social sciences of Western Reserve University, Cleveland, \$10,000 to strengthen the public health nursing practicing field for graduate and undergraduate nursing students.

State Medical Election—Dr Edwin M. Huston, Dayton, was named president-elect of the Ohio State Medical Association at the annual meeting in Cincinnati, October 4, and Dr Ralph R. Hendershott, Tiffin, was installed as president. Next year's meeting will be in Cleveland. Dr Huston was graduated from the Medical College of Ohio, Cincinnati, in 1896.

Society News—A program of graduate lectures will be presented by the Summit County Medical Society, Akron, November 7. Speakers will be Drs. William Wayne Babcock, Philadelphia, who will discuss "Malignant Disease of the Intestine" and "Common Errors in Surgical Practice," Temple S. Fay, Philadelphia, "Important Considerations in the Administration of Fluids" and "Cerebral Injuries and Management of Intracranial Pressure Problems," and John A. Kolmer, Philadelphia, "Vaccination Against Infantile Paralysis" and "Principles and Practical Applications of Chemotherapy." Dr Grover C. Penberthy, Detroit, addressed the Toledo Academy of Medicine, October 4, on "Tannic Acid Treatment of

Burns." Dr Stanley M. Goldhamer, Ann Arbor, Mich., addressed the section on pathology, experimental medicine and bacteriology, October 11, on "Physiology and Treatment of the Macrocytic Anemias."—Dr Elias C. Fischbein, Dayton, addressed the Montgomery County Medical Society, Dayton, November 1, on "Modern Conceptions of the Neuroses."

PENNSYLVANIA

Society News—Dr James W. McConnell, Philadelphia, addressed the Northampton County Medical Society at Easton in September on "The Close Interrelationship of Medicine and Neuropsychiatry."—Dr Charles L. Brown, Philadelphia, discussed differential diagnosis of fever at a meeting of the Berks County Medical Society, Reading, October 8.—Dr Arthur M. Shipley, Baltimore, was guest speaker at the annual meeting of the Cumberland County Medical Society at Carlisle in September, his subject was "Surgery Related to Blood Vessel Diseases."

Philadelphia

Society News—A medicolegal symposium was presented before the Philadelphia County Medical Society at its meeting, October 23, by Drs. Daniel J. McCarthy, Charles W. Burr, William Drayton Jr. and Samuel Leopold and Judge Charles Brown, president of the board of judges. The October 16 meeting was a memorial to the late Dr George A. Knowles, a bronze bust of whom was presented to the society. Dr Knowles, who died in 1934, was assistant director of health of Philadelphia.—Among other speakers before the Physiological Society of Philadelphia, October 21, Dr David L. Drabkin, Mr. A. H. Wideman and Mr. H. Landow presented a paper on "The Fate of Hemoglobin Injected into the Animal Body."—Dr John F. Fulton, New Haven, Conn., was guest speaker at a meeting of the Philadelphia Neurological Society, October 25, his subject was "Recent Experiments on Relation of Frontal Lobes to Cerebellum."

Hospital Survey—In the preliminary report of a survey completed by Harold T. Prentzel, the occupancy of Philadelphia's 19,959 hospital beds is said to have averaged 75.3 per cent in 1934. The report shows that in forty-nine hospitals 50 per cent of the private beds were occupied and 83.4 per cent of the ward beds. Seventy per cent of the unoccupied beds in the city were in the forty general hospitals which have 57.1 per cent of the total number of beds. Fourteen special hospitals having 12.5 per cent of the beds had an occupancy of only 44.4 per cent. The new U. S. Naval Hospital was only 32.8 per cent occupied during the year. Considering all types of beds, the ratio of beds to population in Philadelphia was 10.23 beds per thousand, excluding all special beds, the ratio was 5.84. The investigator concluded that the hospitals with less than 100 beds should be closed or merged with larger hospitals except when they are valuable in serving small communities, that the church hospitals are in unfavorable positions to meet the needs of their constituencies and should meet their environmental conditions, remove to new locations or reduce their capacities, that the centrally located hospitals may have to move or retire from the field, that corporations organized for profit are an economic burden to the public, and that the gap between the use of private and of ward services indicates the necessity for lower cost private service.

Pittsburgh

Society News—Dr Henry M. Ray, Pittsburgh, among others, addressed the Pittsburgh Academy of Medicine, October 22, on "Blood Grouping, Clinical and Medicolegal Applications."—Drs. Ira A. Darling, Warren, and Edward E. Mayer addressed the Pittsburgh Neurological Society, October 21, on "Hospital Treatment of Inebriates" and "Nonpsychotic Conduct Disorders," respectively.

WASHINGTON

Smallpox Increasing—The state health officer reported that Washington had 1,014 cases of smallpox in the first nine months of this year. In 1934 there were 580 cases in the state and in 1933 there were 288.

WEST VIRGINIA

Personal—Dr Frederick T. Foard of the U. S. Public Health Service, who has been in charge of a sanitation program conducted by the state health department and the emergency relief administration, has been transferred to San Francisco. Dr Albert M. Price of the health department will take charge of the sanitation work.

State Health Conference—The annual state health conference was held in Huntington, October 28-30, at the Hotel Prichard. Among the speakers were Drs. Iago Galdston, New

York, on "Health Promotion by Education", Paul Padgett, Baltimore, "Modern Treatment of Syphilis", Henry Kennon Dunham, Cincinnati, "Is Tuberculosis Still a Health Problem?" and Allen W. Freeman, Baltimore, "The Future of Public Health."

Society News—Dr. Richard B. Cattell, Boston, addressed the Ohio County Medical Society, Wheeling, October 25, on "Carcinoma of the Colon and Rectum." Dr. William F. Rienhoff Jr., Baltimore, addressed the society, October 11, on "Surgical Treatment of Diseases of the Lungs and Mediastinum."—Dr. William Wayne Babcock, Philadelphia, addressed the Fayette County Medical Society, Oak Hill, September 28, on "Tumors of the Intestinal Tract."

WISCONSIN

Hobby Exhibit at State Meeting—The Medical Society of Milwaukee County and its Woman's Auxiliary sponsored an exhibit of physicians' hobbies at the annual meeting of the State Medical Society of Wisconsin in Milwaukee recently. Forty-four physicians displayed the following leisure time activities: boat models, photography, collections of rare books, sculpture, sketching, metalcraft, electrical and chemical patents, stamps, butterflies, flowers, a collection of Negro spirituals, third dimension photography and a short wave radio transmitter. The exhibit will be continued at future meetings of the state society.

Society News—Drs. Albert W. Bryan and Jerome T. Jerome, Madison, addressed the Chippewa County Medical Society, Chippewa Falls, September 25, on "Cardiac Lesions and Their Treatment" and "Injuries and Diseases of the Knee Joint," respectively.—Drs. Arthur W. Allen, Boston, and Joseph J. Adamkiewicz addressed the Milwaukee Society of Clinical Surgery, October 22, on "Present-Day Treatment of Head Injuries" and "Common Duct Stones—Their Diagnosis and Treatment," respectively.—Dr. Francis D. Murphy, Milwaukee, was the guest speaker in a symposium on cardiac diseases at a meeting of the First Councilor District of the State Medical Society of Wisconsin in Watertown, October 24.

GENERAL

Southwestern Meeting at El Paso—The twenty-second annual meeting of the Medical and Surgical Association of the Southwest will be held at the Hotel Hussmann, El Paso, November 21-23. Guest speakers, each of whom will make several addresses and conduct clinics and round table discussions, will be Drs. Charles T. Stone, Galveston, Texas, Verne C. Hunt, Los Angeles, Enos Paul Cook, San Jose, Calif., James C. Masson and Louis A. Buie, Rochester, Minn., Hermon C. Bumpus Jr., Pasadena, Isaac H. Jones, Los Angeles, and Albert H. Rowe, Oakland, Calif.

Meeting of Railway Surgeons—The American Association of Railway Surgeons will hold its annual meeting at the Palmer House, Chicago, November 13-15. The tentative program includes the following speakers:

Dr. George W. Hall, Chicago, Mental Reactions Following Trauma
Dr. James E. M. Thomson, Lincoln, Neb., Fractures of the Forearm
Dr. Edward L. Jenkinson, Chicago, Anatomic Variations of the Spine
Dr. Owen H. Wengenstein, Minneapolis, Abdominal Injuries
Dr. George H. Ewell, Madison, Hydrocele: Its Treatment by the Injection Method
Dr. Philip H. Kreuscher, Chicago, Fractures of the Pelvis and Upper End of the Femur

Dr. James Tate Mason, Seattle, President-Elect, American Medical Association, will discuss "Practical Considerations on Intravenous Fluids in Shock, Dehydration and Starvation."

Pacific Coast Obstetric Meeting—The Pacific Coast Society of Obstetrics and Gynecology will hold its annual meeting in Los Angeles, November 6-9, at the Ambassador Hotel. Speakers will include:

Dr. Philip H. Arnot, San Francisco, Morbidity, Mortality and Complications After Cesarean Section
Dr. Herbert M. Evans, Berkeley, Relation of the Anterior Pituitary to the Reproductive Process
Dr. Sterling N. Pierce, Los Angeles, Pseudojaundice of the New Born

A symposium on maternal mortality of seven cities on the Pacific Coast will be presented by Drs. Thomas Floyd Bell, Oakland; Richard J. O'Shea, Seattle; Raymond E. Watkins, Portland, Ore.; Henry A. Stephenson, San Francisco; Clarence W. Page, Berkeley; William Benbow Thompson, Los Angeles; and Thomas F. Wier, San Diego.

The Woman's Auxiliary—The October *News Letter* of the Woman's Auxiliary to the American Medical Association states that in Milwaukee, radio station WTMJ canceled all contracts carrying the radio advertising of internal "patent medicines," an action for which praise is given to the auxiliary of the Medical Society of Milwaukee County. Since the state medical society's approval at the recent annual meeting, a state

organizer in North Dakota is now under consideration, leaving Ohio and Montana the only unorganized states in the north central area. A pilgrimage is being planned in Indiana to visit and care for the graves of the two women who are considered the first in the world to be operated on for an ovarian tumor and disease of the gallbladder. Dr. Ephraim McDowell, Danville, Ky., performed the ovariectomy on Jane Todd Crawford who later lived and is buried in Sullivan, Ind. The second operation was performed by Dr. John Stough Bobbs, June 15, 1867, in Indianapolis, on Mrs. Burasworth, McCordsville. The pilgrimage will also include a visit to the grave of Dr. John L. Richmond, who lived in Indiana and was buried in Covington.

Society News—Dr. Claude W. Munger, director, Grasslands Hospital, Valhalla, N. Y., was chosen president-elect of the American Hospital Association at its meeting in St. Louis, September 30-October 4, and Dr. Robin C. Buerki, superintendent, State University of Wisconsin General Hospital, Madison, was installed as president. Dr. Bert W. Caldwell, executive secretary of the association, was designated editor of the society's official journal, *American Hospitals*.—The National Society for the Prevention of Blindness will hold its annual conference at the headquarters of the society in Rockefeller Center, New York, December 5-7. Among topics to be discussed will be medical social eye work, prevention of eye accidents caused by fireworks, and division of responsibility between official and unofficial agencies in the movement for prevention of blindness.—The sixteenth annual meeting of the American Student Health Association will be held, December 27-28, at the Hotel Pennsylvania, New York.—Dr. Clyde C. Siemons, Lansing, Mich., was elected president of the International Society of Medical Health Officers at the annual meeting in Milwaukee in October.—Dr. John F. Erdmann, New York, was chosen president-elect of the Inter-State Postgraduate Medical Association at the annual session in Detroit, October 18, and Dr. David Riesman, Philadelphia, was installed as president.—At the seventh annual meeting of the Central Association of Obstetricians and Gynecologists in Omaha, October 10-12, Dr. Jean Paul Pratt, Detroit, was chosen president-elect, Dr. Buford G. Hamilton, Kansas City, Mo., was installed as president. Other officers are Drs. James R. Garber, Birmingham, Ala., and Ralph A. Reis, Chicago, vice president and secretary-treasurer, respectively. The next annual meeting will be held in Detroit.

FOREIGN

Scientific Medicine in China—At the annual meeting of the Chinese Medical Association, November 18, in Canton, the one hundredth anniversary of scientific medicine in China will be celebrated. The meeting will be held at Canton Hospital, where Dr. Peter Parker, a medical missionary, first introduced western medicine into the country. A centennial history of the hospital is now in process of publication. A new building for the hospital will be dedicated during the meeting and the foundation stone for a new medical school will be laid.

Society News—At the Seventh International Congress of Industrial Accidents and Occupational Disease at Brussels in July, Dr. Francis D. Donoghue, Boston, was elected vice president and Dr. Robert T. Legge, Berkeley, Calif., a member of the permanent committee. Papers were presented by Drs. Henry H. Kessler, Newark, N. J.; Royd R. Sayers of the U. S. Public Health Service, Washington, D. C.; and Yandell Henderson, Ph.D., New Haven, Conn., among others. The United States delegation was headed by Dr. Claude C. Pierce of the U. S. Public Health Service.—A "Congress on Gout and Uric Acid" was held in Vittel, France, September 14-16. Dr. Hyman I. Goldstein, Camden, N. J., presented a paper on "Gout and the Uric Diathesis."

Nobel Prize in Medicine Awarded to German Scientist—Dr. Hans Spemann, professor of zoology at the University of Freiburg im Breisgau, has received the Nobel Prize in Medicine for 1935 in recognition of his research on embryonic evolution, the *New York Times* reported, October 25. Dr. Spemann is a native of Stuttgart, 66 years old, and studied medicine at the universities of Heidelberg, Munich and Würzburg. He was appointed assistant at the Zoological Institute at Würzburg in 1895 and taught there until 1908 when he was called to the University of Rostock. In 1914 he became director of the Kaiser Wilhelm Institute for Biology in Berlin-Dahlem and was appointed to his present position at Freiburg in 1919. His best known scientific work is entitled "Experimental Research in the Field of Evolutionary Physiology." He is also the author of a manual on the technique of microsurgery. In 1933 he was a guest lecturer at Yale University, New Haven for two weeks.

Government Services

Animal House Planned

The advisory committee on architectural design of the U S Treasury Department has approved a plan for a scientific animal house to be erected for the National Institute of Health on a forty-five acre farm near Bethesda, Md. This site will be developed into an experimental station for the institute under an appropriation of \$100,000, which has been available for some time. The farm was donated by Luke Wilson, retired business man, formerly of Evanston, Ill., from a part of his estate, Tree Tops, on the Rockville pike north of Bethesda.

Memorial to Colonel Hoff

A fountain erected in the circle opposite the main entrance to Walter Reed Hospital, Washington, D C was dedicated October 25, as a memorial to Col John Van Rensselaer Hoff, medical corps, U S Army, who died in 1920. Colonel Hoff was graduated from Albany Medical College in 1871 and from the College of Physicians and Surgeons in the City of New York in 1874. He organized the first detachment of the hospital corps in the army at Fort Reno I T, in 1887, and the first company of instruction hospital corps at Fort Riley, Kan., in 1891. He served through the war with Spain and was chief surgeon of the China relief expedition in August 1900. He was a member of the faculty of the Army Medical School in 1901 and 1902, in 1905 was detailed as observer with the Russian army in the Russo-Japanese war in 1906 was chief surgeon of the Department of Missouri, in 1907 and 1908 chief surgeon of the Philippines division, in 1909 chief surgeon of the Department of the Lakes, and from 1910 until his retirement for age in 1912 chief surgeon of the Department of the East and Eastern Division.

Examination for Reserve Corps of Public Health Service

The U S Public Health Service announces an examination for entrance into the Reserve Corps of the U S Public Health Service in the grade of assistant surgeon, to be held November 18. Boards will be appointed in various cities so as to avoid the necessity for travel, which if necessary must be made at the candidate's expense. Applicants must have graduated from reputable medical colleges and must have had at least one year's internship. They must not have passed their thirtieth birthday. Compensation will be \$3158 per year for an officer with dependents, \$2699 for one without dependents. Successful candidates will be ordered to active duty in the Reserve Corps, in which it is expected there will be vacancies soon after Jan 1, 1936, they will be eligible for examination for entrance into the regular corps when such examinations are held, provided they have not passed their thirty-second birthday. Those who wish to take this examination should request the necessary blanks and other information from the Surgeon General, U S Public Health Service, Washington, D C.

Captain Brister Named Rear Admiral

Promotion of Capt John Mosley Brister, medical corps, U S Navy, to the grade of rear admiral, was approved by the President, October 21. The promotion will be effective January 1 when Rear Admiral Ammen Farenholt will retire, having reached the statutory retirement age of 64 years. Rear Admiral Farenholt is inspector of medical department activities, West Coast, with headquarters at the Naval Hospital in San Diego, Calif. Captain Brister was born in Pennsylvania May 24, 1877, and graduated from the Medico-Chirurgical College of Philadelphia in 1898. He was appointed an assistant surgeon in the medical corps of the navy in 1900. After several years' service on the Asiatic Station and in the Philippines, he returned to the United States for duty at the Philadelphia Naval Hospital. During the World War he was attached to the naval hospital, Boston, and in 1919 and 1920 was in command of the naval hospital, Canacae, P I. He returned to the Boston Naval Hospital in 1921 and in 1923 was transferred to the Naval Hospital at New York. He served as fleet surgeon and aide on the staff of the commander, battle force during 1925 and 1926 and was attached to the bureau of medicine and surgery from 1927 until 1929. He was in command of the Boston Naval Hospital from 1929 until 1933 when he was assigned to his present duties as district medical officer of the fourth naval district, Philadelphia.

The Future of Biochemistry and Pharmacy

At the ninety-fourth session of the School of the Pharmaceutical Society, Sir Frederick Gowland Hopkins, president of the Royal Society and professor of biochemistry at the University of Cambridge, delivered an address on the training of the pharmacist, a subject on which no one else can speak with so much authority. Knowledge concerning the control of the body by a multiplicity of hormones, with complicated inter-relations he said, was growing daily, and the literature of research on vitamins had of late contained as many as 1,000 papers in one year. Only a specialist could deal with such an output. But the fact that substances of the kind were intruding into therapeutics in such an overwhelming way made it desirable that the pharmacist should be aware of the essential facts relating to their origin, distribution and action, and should be fully acquainted with their chemical properties. For this reason he thought that the introduction of animal physiology into the courses of the college was timely. Biochemistry was fast acquiring methods that enabled it to follow the progress of the invisible molecular events occurring in the living tissues. It was progressing on lines that would enable it in the perhaps somewhat distant future to describe in detail the numerous chemical reactions proceeding in ordered sequence in every living tissue cell.

Speaking of the future of pharmaceutical progress, Sir Frederick Hopkins said that it was difficult for those who served the public to avoid supplying it with what it demanded. The public today, and not its humbler sections alone, was for the most part too ignorant to be protected from the influence of advertisements incessantly before its eyes, which proclaimed the supposed merits of a crowd of quack nostrums or expensive proprietary articles of little real value. Many pharmacists did their best to protect it from these and committees were in existence which were considering remedies for the evil. But the problem of combating it, whether by state action or otherwise, was extremely difficult. However, biologic science was gaining a footing in general education. It was beginning in the schools and was increasing its influence in the universities. The time was not far distant when even average members of the community would know much more about their bodies and their bodily functions than they knew today and would no longer display the faith that was born of ignorance.

A Criticism of Freud

In introducing a series of broadcast addresses on social problems from the point of view of a psychoanalyst Dr W R Inge, formerly dean of St Paul's, a man remarkable for the breadth and originality of his views, said that Freud seemed to him to give us psychology without a psyche and to pay too much attention to morbid states instead of investigating the healthy mind. Freud suffered himself from an obsession about sex and this was a misfortune, because there was a tendency to exaggerate enormously the place which sex played in a normal healthy life. Most people thought far more about their work and their play, about earning money and spending it, about their families and friends, than they did about sex. Lastly Freud was wrong in regarding religion as an illusion. His rival Jung was wiser, since he saw that religious faith was a cure in many neurotic cases. Man, who began as an ape afflicted with megalomania was now essentially a savage who fancied himself civilized. He called himself *Homo sapiens* a title which he had done little to earn. Modern man had an almost fatal shock. He looked within himself and found some

very ugly inmates—an earlier psychology would call them evil spirits. Freud taught us to find there only “whited sepulchers full of dead men’s bones and all uncleanness.” Had not saints known that always a psychoneurotic who could say from his heart “I believe in the Holy Spirit” would often get rid of his trouble really and not in imagination? All this evil heritage could be got rid of by the indwelling presence of the spirit of God.

Vitamin Deficiency and Anemia

In the recent extensive literature on the organic and inorganic food factors influencing the formation of hemoglobin, the part played by vitamins has been largely overlooked. At the Royal Infirmary, Edinburgh, D. Melville Dunlop and Harold Scarborough have shown the specific effect of cevitamic acid in the anemia of scurvy. That anemia occurs in scurvy is well known, but until recently it was regarded as due simply to the undernutrition and the hemorrhages, though increased blood destruction has been suggested as an additional factor. But Mettier, Minot and Townsend (*Scurvy in Adults*, *THE JOURNAL*, Oct 11, 1930, p 1089) found that a reticulocyte response could be induced in scorbutic anemia by administering orange juice and suggested that the anemia of scurvy was largely due to prolonged lack of vitamin C affecting the function of the bone marrow. More recently Mettier and Chew have produced evidence that the anemia of experimental scurvy in the guinea-pig is largely dependent on retardation of the maturation of erythrocytes in the bone marrow consequent on a vitamin C deficiency and that orange juice produces a reticulocyte response.

Dunlop and Scarborough studied two cases of scurvy in man (*Edinburgh M J* 42 476 [Sept] 1935). In one the patient was a man, aged 54, who had been unemployed for a long time and for one and one-half years before admission to a hospital had an income of only \$4 a week, of which he spent \$1.50 on his diet. This consisted of bread, margarine, treacle, corned beef or smoked sausage, cheese, and tea made with sugar and canned milk. In the one and one-half years he had never taken fresh vegetables, potatoes, fresh milk or fresh fruit. He felt in poor health and two months before admission noticed numbness in his legs and pains in his knees and calves. About this time his gums became swollen and bled easily. These symptoms progressed, and his legs became intensely painful on walking. Five days before admission he was so incapacitated that he had to go to bed. On admission there were subcutaneous hemorrhages in the lower limbs and pin point ecchymoses over the abdomen. He was given a diet exactly similar to what he had been taking. Its daily iron content was found to be only 10.2 mg, so that there was considerable iron deficiency. He was given orally 60 mg of cevitamic acid daily (equivalent to 3 ounces, or 90 cc, of orange juice) for seventeen days. In this period the red blood corpuscles increased from 2,050,000 to 4,226,000 and the hemoglobin from 45 to 77 per cent. After this he continued on the same deficient diet and no cevitamic acid was given, yet in eleven weeks the corpuscles increased to 5,600,000 and the hemoglobin to 100 per cent. Two days after he began taking the cevitamic acid the pain in the legs was better and three days still later the hemorrhages and other symptoms were receding. Within a fortnight he felt well. After he stopped taking the cevitamic acid the improvement continued for ten weeks. This case shows that cevitamic acid is capable of exerting its beneficial effects for long periods after its administration. The increase of the hemoglobin in spite of the iron-poor diet, is also noteworthy. Dunlop and Scarborough suggest that a deficiency of vitamin C in a diet may be a factor in producing anemia in working class populations even in the absence of symptoms of scurvy.

H W Dudley, Biologist

Harold Ward Dudley, Ph D, F.R.S., a distinguished biochemist, has died at the age of 47 after a short illness. Educated at Leeds University, he came under the influence of the late Prof J B Cohen and in 1910 took the degree of M.Sc. In the same year he was awarded a science research scholarship and worked in Emil Fischer’s laboratory in Berlin with Professor Traube on purine. He next became assistant in the Herter Laboratory, New York, where he came under the influence of H D Dakin. At this time physiologic chemistry was undergoing metamorphosis into biologic chemistry, to which he devoted his life. In collaboration with Dakin he did much original work, comprising the discovery of the enzyme glyoxalase and certain fundamental observations on the racemization of proteins. In 1914-1915 he was lecturer on biochemistry at Leeds University and on the outbreak of the war was attached to the Royal Army Medical College for special chemical work. In 1918 he was in charge of the antigas mission to the United States. After the war he became chief biochemist to the Medical Research Council. At the council’s laboratory he made contributions to biochemistry, including work on the chemistry of the pituitary secretions, insulin, spermine, acetylcholine, histamine and ergometrine. He was secretary of the Biochemical Society from 1922 to 1924 and joint editor of the *Biochemical Journal*. His premature death is a great loss to science.

PARIS

(From Our Regular Correspondent)

Sept. 30, 1935

Prophylaxis of Undulant Fever

At the July 9 meeting of the Academy of Medicine, attention was directed by Barbary of Nice to the necessity of close cooperation of the services of hygiene and veterinary medicine in order to prevent undulant fever. One should remember that, according to recent studies, many new views have been adopted on the two diseases grouped under the heading brucellosis, viz, Malta or undulant fever, due to *Micrococcus melitensis*, and the epizootic abortion of cattle due to the *Bacillus abortus* of Bang. It is essential to familiarize the farmer and cattle raiser, by talks and by pamphlets, with the possibility of contagion, not only through cow’s or goat’s milk (which can be sterilized by boiling) but also with the danger of infection from manure and insanitary conditions in stables and cow sheds. Villages should be subjected to thorough sanitary inspection such as proper sewage disposal, cleaner streets and stables, and fighting of insects, especially mosquitoes. Any one who has visited rural communities in European countries, especially in France, will appreciate the necessity of such sanitary reform measures.

Certain forms of tuberculosis, studied by Dr Mazet, can present a clinical picture resembling that of undulant fever.

In order to discover cases of brucellosis the intradermal reaction with the specific antigen represented by an emulsion of *Brucella abortus* should be used as a routine for cattle, sheep and goats in order to combat undulant fever. Experiments are now being carried out toward attaining a preventive vaccination in human beings.

The Abdominal Form of Migraine in Children

Migraine is seen clinically in young children oftener than in adults, disappearing as a rule at puberty. A history of similar attacks in the child’s family is of much diagnostic importance. The pain is referred to the left or right side of the forehead and in older children is accompanied by nausea and vomiting. In the *Bulletin medical* July 6, Debre and Broca directed attention to the fact that abdominal pain may dominate the clinical picture of the attack of migraine. The

pain is referred to the epigastrium and is accompanied by nausea or vomiting in most cases. The pain may, however, be diffuse, in the form of colics. In the absence of a history of migraine, the diagnosis is difficult. The painful attacks referred to the head may become less frequent, to become more and more abdominal. At times the abdominal form of migraine begins suddenly without a history of a preceding cephalic pain.

The attacks of both cephalic and abdominal migraine end as abruptly as they have begun. A rise of temperature should lead one to question the existence of an abdominal migraine. One must exclude the presence of a tuberculous meningitis, a tumor of the brain, a meningeal hemorrhage and a frontal sinusitis, in cases of the cephalic type of migraine. An appendicitis must be excluded by the less diffuse character of the pain, the absence of muscular rigidity, fever and rise in pulse rate in abdominal migraine. Cyclic vomiting with acetonemia in children presents as the chief symptom the uncontrollable emesis, which ceases suddenly. The authors have, however, observed cases of a combination of abdominal migraine and cyclic vomiting with acetonemia. In a family, an abdominal migraine was found in one child and cyclic vomiting in another. The frequency of migraine in children must be constantly borne in mind. The abdominal form may be mistaken for a condition requiring operative intervention.

Streets Named After Eminent Physicians

It is the custom in French cities to name streets after distinguished citizens. Recently this method of perpetuating the memory of men in the medical profession who have rendered noteworthy services to their fellow citizens has been applied to three streets in Paris, named respectively after Grancher, late professor of pediatrics, Dejerine, the successor of Charcot, and Emile Roux, the former director of the Institut Pasteur.

Bactericidal Action of Carbon Dioxide Gas

The question has arisen recently as to whether carbon dioxide gas can be employed to sterilize water to be used for drinking. To study the problem, Guillerd and Lieffrig allowed a current of carbon dioxide gas to pass through contaminated water for variable periods in order to observe its effects on the bacterial content. Their results were reported at the June 18 meeting of the Academy of Medicine. The rate of flow of the gas was controlled by a manometer. Contrary to certain claims of a bactericidal action of carbon dioxide gas on bacteria in water, the authors found that even when the water is saturated and the gas is allowed to act during a period from thirty minutes to an hour neither colon nor typhoid bacilli are killed.

Birth Rate Continues Downward in France

The excess of deaths over births in the first three months of 1935 has reached the figure of 33,456. During this period only 166,590 births were registered, 10,373 less than in the corresponding period of 1934 and 23,123 less than in the first quarter of 1932.

On the other hand, the number of deaths has increased to 200,046, or 10,802 more than in the first three months of 1934. Of these deaths in 1935, 13,989 were those of infants less than one year old. This is an increase of 398 in spite of the decreased number of births.

The excess of deaths over births during the first three months of 1934 was only 12,282, whereas in the same period of 1935 it is 33,456. This is the largest excess of deaths over births ever registered except during the course of wars or epidemics.

This rapid fall in the French natality figures is particularly disturbing when the increased number of births, 225,000 in 1934, is noted in Germany.

BERLIN

(From Our Regular Correspondent)

Gastro-Intestinal Disease and Infant Mortality

According to Professor Rott in the federal bureau of health, the deaths in Prussia (1926-1932) from diseases of the gastro-intestinal tract in children under 1 year of age were as shown in table 1.

Examination of the table reveals that the males show a higher mortality than the females. In both sexes, however, the mortality from diseases of the gastro intestinal tract is steadily

TABLE 1—Deaths from Diseases of Intestinal Tract

| Year | Males | | Females | |
|------|--------------|----------------------------|--------------|----------------------------|
| | No of Deaths | Per Thousand Living Births | No of Deaths | Per Thousand Living Births |
| 1926 | 6 326 | 16.3 | 4 613 | 12.6 |
| 1927 | 5 015 | 13.6 | 3 548 | 10.3 |
| 1928 | 4 963 | 13.3 | 3 580 | 10.2 |
| 1929 | 5 766 | 15.9 | 4 117 | 12.1 |
| 1930 | 4 118 | 11.6 | 2 891 | 8.6 |
| 1931 | 3 418 | 10.4 | 2 376 | 7.7 |
| 1932 | 3 067 | 9.9 | 2 299 | 7.9 |

regressing, a movement that began about 1905. The downward trend was interrupted during the excessively hot years 1911, 1914, 1917, 1921, 1923 and 1929. Whereas in 1905 about 550 children for each 10,000 living births were carried off by gastro-intestinal diseases, in recent years the number has been brought under 90 per 10,000 living births. In the mortality from gastro-intestinal diseases the well known summer peak has disappeared in various parts of Germany. Today one infant for

TABLE 2—Progressive Reduction in Mortality

| Year | Relative Mortality in Males | Relative Mortality in Females |
|------|-----------------------------|-------------------------------|
| 1903 | 100 | 100 |
| 1913 | 82.6% | 79.7% |
| 1918 | 40.3% | 37.3% |
| 1925 | 35.6% | 31.8% |
| 1930 | 23.6% | 20.1% |
| 1932 | 20.1% | 18.3% |

each 100 living births dies from a gastro-intestinal disease. If one places the mortality from gastro-intestinal diseases for the year 1903 (from which dates the beginning of consistent welfare aid for infants) at 100, table 2 shows the progress that has been made since that year.

Similar results are shown if the deaths from other nursing's disorders, such as eczema, furunculosis, inflammations of the cellular tissues, Barlow's disease, scurvy, rickets, anemias,

TABLE 3—Reduction in Mortality from Other Nursing's Disorders Such as Eczema and Furunculosis

| Year | Relative Mortality in Males | Relative Mortality in Females |
|------|-----------------------------|-------------------------------|
| 1903 | 100 | 100 |
| 1913 | 59.6% | 59.7% |
| 1918 | 58.9% | 56.8% |
| 1925 | 35.1% | 33.7% |
| 1930 | 20.9% | 19.8% |
| 1931 | 19.6% | 18.1% |

diseases of the ear, inflammations of the umbilicus, and, finally, infantile convulsions, are combined and the mortality for 1903 is, as before, placed at 100.

The slide in the downward movement occurred between 1903 and 1913. In this group of diseases also the mortality is today less than one fifth of that recorded for 1903. If the same comparison is applied to the general infant mortality, one gets figures shown in table 4.

Table 4 reveals that the reduction in the general infant mortality is far below that recorded in table 2 for the mortality from gastro-intestinal diseases and in table 3 for eczema, furunculosis, scurvy, rickets, ear disorders, anemias and the like. The general infant mortality today is about two fifths of the mortality for 1903, in spite of the 80 per cent reduction in mortality recorded for the two groups of diseases considered in tables 2 and 3. It is evident, therefore, that the mortality of the first year of life is no longer dominated by the mortality

TABLE 4—*Reduction in the General Infant Mortality Since 1903*

| Year | Relative Mortality in Males | Relative Mortality in Females | Relative Mortality Males and Females |
|------|-----------------------------------|-------------------------------------|---|
| 1903 | 100 | 100 | 100 |
| 1913 | 77 7% | 76 6% | 77 3% |
| 1918 | 78 2% | 76 9% | 77 6% |
| 1925 | 54 7% | 52 4% | 53 7% |
| 1930 | 44 7% | 42 0% | 43 5% |
| 1932 | 41 5% | 40 3% | 41 0% |

from diseases of the digestive tract but rather by the mortality from other diseases (constitutional weakness, influenzal disorders and the like), which were formerly pushed into the background, as it were, by the excessive mortality resulting from diseases of the gastro-intestinal tract.

Almost half of the deaths of infants are due today to constitutional weakness or lack of vitality, a seventh to influenzal disorders, including pneumonia, and about one fourth to diseases of the digestive tract and to other nurslings disorders such as eczema, furunculosis, scurvy and rickets. The deaths from diseases of the digestive tract now constitute only one ninth of the infant mortality in 1903 they amounted to one fourth. The situation, as compared with the first two decades of this century, has changed so that, in the nutritional problems of the infant, morbidity plays a more important part than mortality. In general, the combating of infant mortality, with the increasing elimination of the diseases controlled by environment, is shifting more and more in the direction of hereditary biology and constitutional history.

The Crusade Against Tuberculosis

At a meeting of the National Federation for the Combating of Tuberculosis, Greppi spoke on purpura tuberculosa and generalized tuberculosis with episodes of purpura and with vascular signs of hemorrhagic diathesis. In benign purpura with a tuberculous substratum, clinical observations have shown the benefits derivable from splenectomy, as in the field of hemorrhagic syndromes, with a deficiency of blood platelets.

Zurria pointed out that osteo-articular tuberculosis is not following the descending curve that has characterized the pulmonary types for years. In view of the frequent coexistence of visceral lesions in patients with osteo-articular tuberculosis, especially in children, he emphasized the need of sanatoriums for the treatment of osteo-articular tuberculosis.

Fichera described the results of phrenic exeresis. The immediate results of this method have aroused enthusiasm, some authors believing that it may replace pneumothorax in the treatment of pulmonary tuberculosis. According to the author, phrenicectomy has a more limited value than was at first supposed. While it is an adjunct of collapse therapy it does not have a marked curative action. There is rarely a permanent cure. Often the good effects are of short duration. The cavities at the base of the lung are the lesions that derive the greatest benefit. The operation is not exempt from damage and complications.

Giuffrida spoke on the importance of the problem as to when pneumothorax should be interrupted. In exudative types, the treatment should not be extended over a long period. In the mixed types, and in the productive types, which heal by way of fibrosis, and in the types in which recurrences are frequent, it is necessary to continue the treatment longer.

Gualdi spoke on the spontaneous healing of early cavities and advanced three different explanations.

Randone made a contribution on the dissociation of the Koch bacillus, presenting and describing a strain of acid resistant and alcohol-resistant bacillus that he isolated in 1930 from the sputum of a tuberculous patient. The strain had as characteristics a yellowish pigmentation and a creamy consistency, which are characters of stability. The speaker thinks that it was a variety of Koch bacillus that possessed the combined characters of the variants S and Ch.

Zito, in studying patients with pulmonary tuberculosis during the application of collapse therapy, discovered that the uvula undergoes deviations from its median position. In hypotensive pneumothorax the uvula is turned toward the side of the pneumothorax, whereas the contrary is true if the pneumothorax is hypertensive. In bilateral pneumothorax the deviation is toward the side on which the lung is less expanded.

League of Mental Hygiene

The League of Hygiene and Mental Prophylaxis held its session in Bari. Professor D'Antona discussed the nature of psychiatric aid in the region of Apulia and Lucania. For about three million people there is a psychiatric hospital and an institute for mental defectives. A new hospital is about to be opened. Professor D'Antona proposed that neuropsychiatric dispensaries be established in all the principal centers, that a census be made of the mentally abnormal children in the elementary schools and in the prisons for minors, and that in the higher courses of instruction and in the schools for nurses a part of the instruction be reserved for neuropsychiatric aid, in order to train a suitable personnel for welfare aid work.

Protection for Mother and Child

During 1934 the Opera nazionale per la protezione della maternità e infanzia supplied aid through admission to various institutions, to 1,096,567 expectant and nursing mothers and children. In addition, 73,161 unmarried pregnant women and mothers, and abandoned and delinquent children, have received aid of a moral character, in observation centers and institutes for reeducation. The legal recognition of natural children has been effected and illegitimate unions have been legalized. The distribution of 8,654 marriage and birth premiums has been made, while 17,910 mothers have been given special premiums for giving children proper hygienic care. During the year 8,535 institutes needed for the carrying on of the work have been created, including obstetric and pediatric consultation centers, maternal refectories and milk stations.

Hospital Exhibits

In connection with the International Congress of Hospitals, an exposition of Italian hospitals and an exhibit of hospital equipment were organized. The army medical corps contributed a display of plaster casts and documents from some of its newer hospitals. Likewise, an exhibit was furnished by the institute of social insurance, to which are entrusted the functioning of compulsory insurance against tuberculosis and the construction and management of sanatoriums. Special exhibits were organized by the hospitals of Milan, Rome, Leghorn and Brescia. The Brescia Hospital is one of the largest and most modern hospital buildings in Italy, with a total of 1,450 beds. From a central octagonal court radiate eight separate buildings. In this hospital there is a distinct separation between the movements of persons on the ground floor and the transportation

of equipment and materials, which is effected through two distinct corridors on the floor below, the aseptic service (drugs, food supplies and linen) being confined to one corridor, and the septic service (truck loads, garments of patients, sweepings and refuse) to the other corridor. The services are organized in such an effective manner that in less than five minutes food from the kitchen or drugs from the pharmacy can be carried to any department. The practicable construction of the hospital is reflected also in the cost of erection, which does not exceed 14,000 lire (\$1120) per sick-bed, which may be regarded as a record in economy.

VIENNA

Sept. 8, 1935

Infant Mortality in Austria

A recently published report of the Austrian public health service reveals the beneficial effects on infant mortality resulting from the systematic aid given to infants and mothers. After the close of the World War, similar observations were reported from all countries affected, first an increase and later a rapid decline in the birth rate. In the republic of Austria 137,372 living births were recorded in 1920. The next year showed a 4 per cent increase, and the following year a 7 per cent increase, but then a distinct decline set in, which in twelve years amounted to more than 40 per cent (a drop from 150,800 in 1922 to 90,924 in 1934). In Austria no attempts on the part of the government were made to raise the birth rate by the granting of financial rewards. Instead, the decline of the population was combated by endeavoring to reduce the infant morbidity and mortality. This was accomplished by appointment of an "Executiv-Comité der Säuglings- und Kleinkinder-Fürsorge," and the aid of the ministry for social administration and of the local health bureaus. The 104 consultation centers for mothers were further developed and new centers were added, so that now there are 492 such centers. In addition, seventy-eight supplementary centers were established in rural districts, also thirteen consultation centers for pregnant women. A special scientific committee, with which the leading pediatricians, the heads of the local health boards, and the officials of the ministry and of the municipal bureaus cooperate, has worked out a system according to which in the centers, 515 physicians and 530 trained nurses give professional advice to the mothers of infants up to 1 year of age, all without charge. About 100,000 children were supervised last year, more than the total number of births for the year. The results are satisfactory. Whereas in 1920 the infant mortality was 157 per thousand living births the mortality rate has declined every year except one (1928)—more rapidly, in fact, than the birth rate. The infant mortality rate was 117 per thousand living births for 1925, 106 for 1930 and 91 for 1934, which is a reduction of 45 per cent. The absolute number of deaths among children under 1 year shows a corresponding decrease: 1920, 22,762 deaths, 1925, 15,895, 1930, 11,665, 1934, 8,821. It must not be forgotten, however, that the number of births has declined by 40 per cent. Nevertheless a comparison of the deaths in 1920 (22,762) with the deaths in 1934 (8,821) brings out the fact that the deaths of children under 1 year of age have declined by 63 per cent. Expenditures in the amount of 773,000 Austrian shillings (about \$150,000) were borne by the ministry of health and the next few years will doubtless bring still higher expenditures, because further development of the centers in the rural districts and more particularly in the mountain regions, is an urgent need. The cities, such as Vienna, are adequately provided for. A model institution, which has been studied by the governments of many different countries is the Reichsanstalt für Mutter- und Säuglingsfürsorge, another excellent institution is the Central-Kinderheim der Gemeinde Wien.

Rôle of the Stomach in Hematopoiesis in Anemic Persons

Some time ago, Professor Bence of Budapest, as a guest of the Society of Internal Medicine, delivered a lecture in Vienna on the rôle of the stomach in hematopoiesis, of which the following is a digest. By the single injection of large doses of active liver extract (20 cc.) a remission of several months is regularly effected. This is a sure test of the potency of a liver extract. Bence removed the stomach of hogs and after a few months tested their livers as to the antianemic potency, which was found to be lost. In the gastrectomized animals there developed, from five to six months after the operation, a microcytic anemia such as is occasionally observed also in man following gastrectomy. From nine to twelve months after removal of the stomach, the experimental animals developed a hypochromic blood picture, with reduced diameter of the erythrocytes (3.8 microns). Two animals that were not killed to determine the antianemic potency of their livers, as were the others, survived the operation by seventeen and twenty-one months, respectively. Both these animals presented, during the last months of their existence, a transformation of their microcytic, hypochromic blood picture into a macrocytic anemia with increased color index and diameter of the erythrocytes up to 8.8 microns, at the same time there was a reduction in the leukocyte count and the thrombocytes amounting to from 40 to 50 per cent, together with increase of the bilirubin in the blood serum. At necropsy the spleen and liver were found to be of normal size, and no hemosiderosis, in contrast with the observations on pernicious anemia in man. In all long bones there were found large quantities of active red bone marrow, in which the formation not only of red but also of white blood corpuscles was increased to embryonic proportions. There were also a few megaloblasts. Bence believes that also in man pernicious anemia presents in the beginning stages a microcytic, hypochromic alteration of the blood picture, but it is not open to medical observation.

The liver of the gastrectomized animals (hogs) shows a progressive reduction of its copper content down to a few slight traces while examination of commercial liver preparations discloses that their potency increases in direct proportion to their copper content. In human blood the normal copper level is 0.94 mg per hundred cubic centimeters. During pregnancy it may be increased to 1.94 mg, probably because considerable quantities of copper must be directed to the embryonic liver. In pernicious anemia one observes also an increase of the copper level up to 1.42 mg, also secondary anemia shows such a behavior. On the other hand, in syphilitic anemia and anemia associated with carcinoma, which show no increase in blood formation, low values ranging around 0.5 to 0.7 mg per hundred cubic centimeters are found. Professor Bence holds therefore, to the conception that to the stomach may be assigned a dominant qualitative and to copper metabolism more of a quantitative rôle in hematopoiesis.

The Vienna Emergency Relief Society

The Wiener freiwillige Rettungsgesellschaft, which may be solicited in the event of any accident on the street or in the homes has rendered aid in 15,000 accidents. There were 26,685 patients involved, who were given aid without consideration as to social station, nationality or religious affiliation, all without charge. The recently published report announces an increase in the number of suicides: 339 men, 282 women, two children under 14 years of age. In addition there were 680 men and 872 women who failed in their attempt. Most of the suicides used illuminating gas next came poisoning then hanging, then firearms. The most suicides occurred in April, the next largest number in March and the fewest in September. In factories and machine shops, September is the most dangerous month for accidents, July coming second. The highest figure for accidents

in general was reached in 1934 in July (2,675 accidents in Vienna), next came September with 2,531 accidents, while the fewest occurred in January (1,181). Another task of the Rettungsgesellschaft is to transport to a hospital or to the police station intoxicated persons found injured on the street. In this section wine is the most common alcoholic beverage. August appears to be the most dangerous month for the wine drinkers (seventy-four cases), while Christmas celebrations make December a close second (sixty-three cases). The number of accidents among men is nearly twice as great as among women, likewise in street accidents the proportion remains about the same (630 men, 390 women). Eighty-seven men and seventy women had to be brought to the psychiatric clinic. Of the victims of automobile accidents 1,233 were men and 402 were women (3:1), in railway accidents forty-six men and five women were involved, in street railway accidents, 234 men, 134 women and 22 children. Of the 531 bicyclists suffering accidents 348 were men, 136 women and 47 children (under 14 years).

Professor Dr Anton Eiselsberg

Prof Anton von Eiselsberg, Austria's most eminent surgeon, has celebrated his seventy-fifth birthday and is still in full possession of his mental and physical vigor. When in 1884 he took his doctor's degree in Vienna he had pursued his medical studies in many of the leading universities of Europe. He was Billroth's favorite pupil and became his assistant in 1887. Two years later he became privatdozent, and at the age of 33 he was called to Utrecht and then to Königsberg. In 1901 he accepted a similar position in Vienna, where he did pioneer work for thirty years as physician, instructor, investigator and surgeon. His researches on erysipelas, sepsis, anthrax and tetanus were milestones in the history of surgery. Surgery of the thyroid and of the parathyroids owes its first development to Eiselsberg. He devoted himself particularly to the problem of cancer, and he transplanted the first sarcoma to the rat. His surgical interventions on the cranium made his name known in all countries. At his clinic, of which the emergency station is an important part, the cardiac suture and blood transfusion were perfected in their technique. The railway emergency service owes its existence chiefly to him. He has been an earnest opponent of the abuse of alcoholic beverages and against the antivivisectionists. Eiselsberg founded in Vienna what is virtually a "school" of surgery. His pupils may be found in many of the surgical clinics and hospitals of central Europe. He is doctor honoris causa of many universities, he is the possessor of the Lister gold medal (a high distinction in England) and has been the recipient of countless honors and has held innumerable positions of honor. Evidence of his modesty and retiring disposition may be derived from the fact that he refused to accept the holding of any ceremonies in honor of his seventy-fifth birthday and spent the day in quiet. But all his many admirers express the ardent wish *ad multos annos!*

Increase in Physicians in Vienna

The municipal bureau of health, which exercises supervision over the medical personnel of Vienna, reports that the number of physicians is still on the increase. At the end of 1930 there were 4,651 physicians in Vienna, 475 of whom were women. At the end of 1934 there were 4,732 physicians, 500 of whom were women. The dentists show a similar increase, there having been in 1930 1,726 physician-dentists (*zahnärzte*) and "dentists" (*zahntechniker*) combined, while in 1934 the number had increased to 1,823. There is thus one physician to every 380 inhabitants, and one physician dentist or "dentist" to every thousand inhabitants. It should be noted, however, that of the 4,732 registered physicians about 900 are hospital physicians who have no private practice and who, after completion of their hospital service, will likely settle in the provinces, outside of Vienna.

Marriages

HARRIS HILLMAN PALMER, Orangeburg, N. Y., to Miss Jessie Speirs Travis of Monsey in Spring Valley, June 29.

CLARENCE HOGUE INGRAM JR., Pittsburgh, to Miss Mary Katherine Evans of New Rochelle, N. Y., July 10.

JAMES REY SHOLL, St. Petersburg, Fla., to Mrs. Betty Belcher of Charleston, W. Va., in Chicago, June 2.

HENRY HARRIS DREWRY to Dr. Virginia MacDonald Moore, both of New York, in Elizabeth, N. J., September 4.

WALLACE TREZER SMITH, East Rockaway, N. Y., to Miss Marian M. Walbancke of Richmond Hill, July 21.

WILLIAM FREEMAN to Miss Gertrude Leah Le Clair, both of Worcester, Mass., in New York, October 11.

JOHN WALTER HOUK, Akron, Ohio, to Miss Mary Hammond O'Brien of New Haven, Conn., July 27.

WILLIAM G. HAMM, Atlanta, Ga., to Mrs. Katharine Cathcart Moore of Charleston, S. C., August 28.

WILLIAM O. WUESTER JR., New York, to Miss Janet Evelyn Hampsh in Pompton Lakes, N. J., July 20.

SHERMER HAINES STRADLEY to Miss Margaret Elizabeth Spencer, both of Wilmington, Del., July 1.

WILLIAM M. NETHERY, Lovelock, Nev., to Miss Jessie Mae Elmore of Shreveport, La., September 22.

KENNETH G. KOHLSTAEDT, Indianapolis, to Miss La Verne Freeman of Bloomington, Ind., July 14.

OTIS GARDNER KING, Bluefield, W. Va., to Miss Mayble Isobel Lawrence of Ashland, October 8.

JAMES EDWIN THOMPSON to Miss Ethel Bartlett, both of New York, in Litchfield, Conn., July 6.

EDWIN KENNEDY PROVOST, Nashville, Tenn., to Miss Edith Morgan Cassidy of Cincinnati in June.

PHILIP B. GREENE, Spokane, Wash., to Miss Marjorie Wilcoxson in Springfield, Ill., August 17.

RAY L. RHYMES JR. to Miss Bessie Budhill, both of Houston, Texas, in Shreveport, La., July 1.

WADE BISHOP ELLIS, Buffalo, to Miss Catherine Mowat of Long Island City, N. Y., October 10.

HORACE H. HOLT, Nashville, Tenn., to Miss Elizabeth Abbie Seale of Greenshaw, Miss., July 18.

ALVA A. JACKSON, Florence, Ala., to Mrs. Marguerite Smith in Nashville, Tenn., July 25.

MICHAEL WILLIAM HOLEHAN to Miss Elizabeth Weathersby, both of Memphis, Tenn., July 20.

WILLIAM T. SALTER, Boston, to Miss Eleanor Vallandigham of Chestnut Hill, Mass., June 27.

FRANCIS SAMUEL DIXON to Miss Virginia Waldo Butler, both of Natchez, Miss., September 14.

JAMES WYATTE TARRANT JR., Philadelphia, to Miss Marguerite Sinquefeld, October 15.

JOHN YOUNG O'DANIEL, Erwin, Tenn., to Miss Betty Matthews of Dayton, October 12.

SHELDON C. BAJEMA, Wallace, Idaho, to Miss Lois Horton of Bonners Ferry, August 21.

PETER E. SABATELLE to Miss Vivian Cowart, both of Brooklyn, in Atlanta, Ga., June 18.

WILLIAM B. SWIGERT, Denver, to Miss Ruth E. Anderson of Ogallala, Neb., July 12.

CLIFFORD A. LUTGEN, Auburn, Neb., to Miss Edna Hanke of Nebraska City, July 10.

REUBEN A. MACBRAYER to Miss Myrtle Florence Fox, both of Brooklyn, October 5.

LORENZ TEER, Delhi, La., to Miss Madeline Haughton in Haynesville, June 16.

JOHN C. RIGGINS, Tucson, Ariz., to Miss Rachel Thompson in Bisbee, June 28.

ALLYN KING FOSTER JR., Brooklyn, to Miss Elsa Margareta Nilsson, October 4.

JOHN A. RIEBEL II to Miss Gayle Stevens, both of Hamilton, Ohio, June 30.

KARL M. BECK to Miss Fannie Manley, both of Waukegan, Ill., September 20.

GILBERT E. SCHOENFELD to Miss Fern Niman, both of Detroit, June 2.

BARRETT L. TAUSSIG, St. Louis, to Miss Margaret Humphreys in June.

Deaths

Joseph Colt Bloodgood ♂ adjunct professor of surgery, Johns Hopkins University School of Medicine, Baltimore, and head of the laboratory of surgical pathology, died suddenly, October 22, in Baltimore, of coronary thrombosis. Dr. Bloodgood was born in Milwaukee, Nov. 1, 1867. He received the degree of bachelor of science from the University of Wisconsin in 1888, and that of doctor of medicine from the University of Pennsylvania Department of Medicine, Philadelphia, 1891. The following year he served as assistant resident surgeon to the Johns Hopkins Hospital and then went abroad to study. On returning from Europe in 1893 he became resident surgeon at the Johns Hopkins Hospital. At various times he was assistant instructor, associate in surgery and associate professor of clinical surgery and clinical professor of surgery at Johns Hopkins University School of Medicine. He was one of the founders and a member of the board of directors of the American Society for the Control of Cancer, a member of the American Surgical Association, the Southern Surgical Association, the Society of Clinical Surgery, the American Association for Cancer Research, the American Public Health Association and the Deutsche Gesellschaft für Chirurgie, and a fellow of the American College of Surgeons. He was a member of the Radiological Society of North America which in 1929 awarded him a gold medal for his study of malignant conditions of bone and their diagnosis and treatment by means of x-rays and radium. When the United States entered the World War in 1917 he was commissioned a major in the medical reserve corps of the U. S. Army, he was made a member of the medical section of the National Council of Defense and also of the national medical commission of the American Red Cross. Dr. Bloodgood was assistant visiting surgeon to the medical staff of the Johns Hopkins Hospital and Dispensary and chief surgeon to St. Agnes' Hospital, and was on the editorial board of the *American Journal of Cancer*. He contributed to the periodical medical literature and traveled widely to address public and professional audiences, chiefly on the subject of the early diagnosis and the prevention of cancer.

Acme
JOSEPH COLT BLOODGOOD, M.D.
1867-1935

Mortimer Williams Raynor ♂ White Plains, N. Y., Syracuse University College of Medicine, 1904, professor of clinical psychiatry, Cornell University Medical College, New York, formerly assistant professor of psychiatry and clinical professor of psychiatry, Columbia University College of Physicians and Surgeons, member of the American Psychiatric Association and the Association for Research in Nervous and Mental Diseases, past president of the Medical Society of the County of Westchester, the New York Psychiatric Society and the New York Society of Clinical Psychiatry, served during the World War at one time psychiatrist of the Department of Correction, stationed at Welfare Island, chairman of the executive committee of the Mental Hygiene Committee of the State Charities Aid Association, assistant physician to the Hudson River State Hospital Poughkeepsie 1907-1917, director of clinical psychiatry, Manhattan State Hospital, New York, 1917-1923 and assistant physician 1923-1924, consultant psychiatrist and neurologist, St. Francis Hospital Poughkeepsie, 1915-1917, adjunct associate consultant to the Children's Hospital, New York, 1920-1924, visiting neurologist to the Letchworth Village, Tithells, N. Y., 1923-1924, medical superintendent of the Kings Park (N. Y.) State Hospital, 1924-1926, member of the board of visitors of the New York State Reformatory for Women Bedford 1929-1930, on the staffs of

the Grasslands Hospital, Valhalla, N. Y., and the New York Hospital, medical director of the Bloomingdale Hospital, aged 56, died, October 5.

Frederick Petheram Wilbur ♂ Franklin, N. J., Johns Hopkins University School of Medicine, Baltimore, 1906, executive secretary of the Sussex County Medical Society, formerly member of the board of education and president of the board of health of Franklin, a member of the medical staff of the Alexander Linn Hospital, Sussex, the Newton (N. J.) Hospital and the Franklin Hospital, aged 55, died suddenly, September 8, of angina pectoris.

William W. Jackson, Jonesboro, Ark., Memphis (Tenn.) Hospital Medical College, 1896, member of the Arkansas Medical Society, past president of the Craighead-Ponsett Counties Medical Society, formerly president of the city board of health and member of the state board of health, on the staff of St. Bernard's Hospital, aged 72, died, September 7, of nephritis and myocarditis.

William D. Porter ♂ Cincinnati, Medical College of Ohio, Cincinnati 1887, professor emeritus of clinical obstetrics, University of Cincinnati College of Medicine, past president of the Cincinnati Academy of Medicine, at various times on the staffs of the Bethesda Hospital, Cincinnati General Hospital and the Jewish Hospital, aged 74, died, September 27, of heart disease.

John Bryant ♂ Brookline, Mass., Harvard University Medical School, Boston 1907, member of the New England Pediatric Society, member and past president and secretary of the American Gastro-Enterological Association, served during the World War, aged 54, died, September 19, of cerebral hemorrhage.

Will Lyman Griffin, Shelby, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888, member of the Michigan State Medical Society, past president of the Oceana County Medical Society, on the staff of the Shelby Community Hospital, aged 76, died, September 5.

William Shelton Osborn, Osage, Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1904, member of the Iowa State Medical Society, veteran of the Spanish-American War, aged 58, died, September 3, in a hospital at Rochester, Minn., of embolism.

Wilfred G. Riopelle ♂ Beaver Dam, Wis., Marquette University School of Medicine, Milwaukee, 1915, past president of the Dodge County Medical Society, aged 46, died, September 9, in St. Joseph's Hospital, Milwaukee, of heart disease.

Theodore Elmer Jeffery, St. Augustine, Fla., Arkansas Industrial University Medical Department, Little Rock, 1898, member of the Arkansas Medical Society, served during the World War, aged 62, died, September 5, of cerebral hemorrhage.

Thomas William Wilson, New Harmony, Ind., Miami Medical College, Cincinnati, 1887, member of the Indiana State Medical Association, health officer of New Harmony, aged 74, died, September 1, of coronary sclerosis and angina pectoris.

Van Buren Dudley Viets, Youngstown, Ohio, Eclectic Medical Institute, Cincinnati, 1895, member of the Ohio State Medical Association, aged 64, died, August 22, in the North Side Unit of the Youngstown Hospital, of cerebral hemorrhage.

Van Noyes Verplanck, New York, Johns Hopkins University School of Medicine, Baltimore, 1918, member of the Medical Society of the State of New York, aged 44, died, September 11, of gastritis due to cyanide poisoning.

John Morgan Hackley, Miami, Fla., University of Louisville (Ky.) Medical Department, 1891, served during the World War, aged 69, died, September 2, in the Veterans Administration Facility, Augusta, Ga., of bronchopneumonia.

James Vincent Nigrelli, Wakefield, R. I., Tufts College Medical School, Boston, 1932, served during the World War, aged 36, on the staff of the South County Hospital where he died, August 10, of an infection of the throat.

Isidor Topkins, Calton, N. J., Long Island College Hospital, Brooklyn 1899, past president of the Hunterdon County Medical Society, aged 64, died, September 2, at Newark, of coronary sclerosis and pulmonary infarction.

Albert Pfeiffer ♂ Albany, N. Y., L.R.C.P., London and M.R.C.S. England, 1911, served during the World War, director of social hygiene, New York State Department of Health, aged 53, died, September 24.

John C. White, Atlanta, Ga., Southern Medical College, Atlanta, 1889, member of the Medical Association of Georgia, formerly member of the state legislature, aged 76, died September 7, of heart disease.

John H Daugherty, Glendale, Calif., Central College of Physicians and Surgeons, Indianapolis, 1881, aged 76, died, July 12, in the Glendale Sanitarium, of acute suppurative appendicitis and peritonitis

John Arthur True ☉ Spokane, Wash., University of Michigan Homeopathic Medical School, Ann Arbor, 1912, served during the World War, aged 47, died, July 26, in the Deaconess Hospital, of brain tumor

Frank Stage Rarey, Columbus, Ohio, Starling Medical College, Columbus, 1892, member of the Ohio State Medical Association, aged 80, died, September 7, in the Mount Carmel Hospital, of uremia

Thomas Allen Lamb, Alexandria, Va., College of Physicians and Surgeons, Baltimore, 1915, member of the West Virginia State Medical Association, aged 47, died, August 30, in Port Republic

Louis Douglas Stoner, Sophia, W. Va. University and Bellevue Hospital Medical College, 1927 member of the West Virginia State Medical Association, aged 33, died, August 14, of pneumonia

Eugene P Nolan, Chicago, Bennett Medical College, Chicago, 1915 on the staff of St Mary of Nazareth Hospital, aged 54, died, August 16, of arteriosclerosis and coronary thrombosis

Richard Alonzo Napier, Union City, Tenn., University of Nashville Medical Department, 1900, aged 62, died, September 7, in St Thomas Hospital, Nashville, of cardiorenal disease

Lewis Henry Campbell, Bradford, Ont., Canada, M. B., University of Toronto Faculty of Medicine, 1892, Victoria University Medical Department, Coburg, 1892, died, August 19

Clifford Sutherland Losey, Long Beach, Calif., Rush Medical College, Chicago, 1897, aged 60, died, August 11, in the Seaside Hospital, of cerebral thrombosis and arteriosclerosis

Josiah Peet Bixby, Woburn, Mass., Medical School of Maine, Portland 1876, member of the Massachusetts Medical Society, aged 80, died, September 1, of cerebral hemorrhage

Bernard Berens, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1880, aged 77, died, September 12, of thrombosis of veins of the leg

Robert Thomas Saville, Mineville, N. Y., University of the City of New York Medical Department, 1881, aged 85, died, August 4, of carcinoma of the prostate.

Philip August Bill ☉ San Francisco, University of California Medical Department, 1902, aged 54, died, August 27, of coronary thrombosis and angina pectoris

Joseph Stephen Thorne, North Evans, N. Y., University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1896, died, August 11, of pulmonary tuberculosis

Bureau of Investigation

ORTHOPEDIC FOOTWEAR, INC

A Warning to Physicians

A physician in Mississippi was called on July 30 by one Wilbert Briggs, who showed credentials to the effect that he represented "Orthopedic Footwear, Inc.," 410 Woolworth Building, Providence, R. I. The physician gave Briggs an order for a pair of shoes for his little girl and a so-called Cushion Arch Lift for his wife. The list price of the shoes was given as \$9.50 and of the Arch Lift as \$3.50, but Briggs stated that a special price was made to physicians of \$6.50 and \$2, respectively. Briggs was paid the full amount (\$8.50) and gave a receipt for both the shoes and for the Arch Lift on a duplicate order-blank, on each of which was written "Paid in full." However, printed on the same receipt order-blank was the statement "Pay only amount of deposit to salesman. Pay the balance to the postman."

On August 9, ten days after the order was given, the physician wrote to Orthopedic Footwear, Inc., asking that the order given representative Briggs for a pair of black shoes be changed to white. Orthopedic Footwear, Inc., did not answer the letter until nearly two weeks later—August 22—at which time they

Reproduction (reduced) of the order slip used by Orthopedic Footwear Inc. earlier known as Orthopedics Inc. and still earlier known as Wilbert Briggs Inc. The order slip reproduced is a specimen copy sent to the Bureau of Investigation by the company and has been marked by the company to call attention to the fact that the doctor who paid the agent the full price should not have done so. On the duplicate order slip that was left with the doctor agent Wilbert Briggs had written "Paid in full."

stated that they had no record of having received the doctor's orders, and asked him to send them the receipts that he had received and at the same time let them know the exact amount of cash which he had paid to Briggs. The physician sent the receipts as requested and stated the amount that he had paid Briggs. In the same letter he mentioned the fact that several other citizens of his town had paid Briggs amounts varying from about \$2 to \$20 and none had either heard anything regarding their orders nor received any merchandise.

This letter accompanying the receipts was sent on August 26. After waiting another three weeks—until September 14—and getting no acknowledgment from Orthopedic Footwear, Inc., the physician again wrote them, reminding them that he had received no reply. He let them know, also, that he had had photostatic copies of the receipts made before he parted with them and he stated, further, that unless some satisfactory adjustment was made he would take the matter up with the American Medical Association so that other members of the profession could be protected. This letter brought a fairly prompt reply from Orthopedic Footwear, Inc., returning the receipts and calling attention to the statement printed on the receipts

which read "Salesman not authorized to alter printed terms on this order" They also called attention to the further statement at the bottom of the receipt reading "Above completes agreement of parties No other statements binding" Orthopedic Footwear, Inc., emphasized, what has already been mentioned, that the blanks specifically state that persons placing orders should pay only the amount of deposit to the salesman, the balance being paid the mailman The company also stated that they had "written Mr Briggs very strongly," but that they doubted if their letters would reach him, as they had not heard from him for some time and that, in fact, two of their letters had already been returned unclaimed!

The only adjustment that the concern offered read as follows

"Now covering the order for Arch Lifts for Mrs ———, we are willing to mail the Arch Lifts to her C O D balance of \$1 50 plus postage In the case of the little girl, we want to say that the price of the shoes is \$9 50 plus postage consequently, there is a balance due of \$3 00 on same We are willing to mail the pair of shoes C O D \$6 50 plus postage (we must receive at least \$6 50 for each pair shoes mailed from here) The amount of \$3 50 which you will have overpaid on this order will be refunded to you as soon as the order and money have been received from Mr Briggs"

A letter was written by the Bureau of Investigation to Orthopedic Footwear, Inc., referring to the physician's experience and the concern was asked in effect what it intended doing In reply the company disclaimed any moral responsibility and reiterated that the physician was in error in paying agent Briggs in full The letter closed on this note

"We are trying in every way possible to straighten these matters out, and it is our intention to mail the goods to the people as soon as we are paid for them by Mr Briggs" [Italics ours—Ed]

In other words, it seemed to be a case of "Heads I win, tails you lose."

Investigation indicates that "Orthopedic Footwear, Inc." is a Delaware corporation, incorporated Feb 25 1935 It is a later name for what was previously known as "Orthopedics, Inc.," another Delaware corporation incorporated in May 1928 This in turn, was a later name for what used to be called "Orthopedic Shoe, Inc." The president of the company seems to be one Arnold C Messler, while the secretary-treasurer is his wife, M C Messler It is reported that A C Messler had previously been in the jewelry business both in Pawtucket and in Providence, but that the concern went into involuntary bankruptcy The present business is said to consist in retailing shoes through agents and on the mail-order plan from Room 410 in the Woolworth Building, Providence, R I The visible resources of Orthopedic Footwear, Inc., seem to be extremely limited

It is of further interest in this connection to note that the Better Business Bureau of Providence, R I, in its bulletin for May 1935 published an item reading as follows

"Orthopedics, Inc., Woolworth Bldg, Providence, a retailer of shoes selling direct to consumers through agents located in various parts of the country, has been the subject of numerous complaints from people who alleged that shoes for which deposits or full amounts had been paid were not forthcoming from the concern and that in instances where shoes were delivered wrong sizes were received and returned and that no shoes of the proper size or a refund of money had been made Complaints received against the firm have been referred to government authorities Orthopedics Inc is recorded as operated by Arnold Messler M C Messler and M C Littlefield

The physician's experience with Orthopedic Footwear Inc. again emphasizes the risk that is run in paying money to unknown agents of equally unknown concerns If it seems desirable to do business with concerns about which the physician knows nothing, the suggestion should be made that the money be placed in escrow with a local bank, on the understanding that it will be paid over to the mercantile concern when the doctor has had the opportunity of determining whether the merchandise ordered comes up to the claims made for it

Correspondence

HYPERGLYCEMIA AND ARTERIOSCLEROSIS

To the Editor—In a communication from Dr Eli Moschcowitz with the title "Hyperglycemia" (THE JOURNAL, September 28 p 1057) is a criticism of the general opinion that diabetes is a contributing factor in the causation of arteriosclerosis Dr Moschcowitz not only disagrees with that opinion but accuses many writers of confusing arteriosclerosis with the lipid imbibition of the aorta found among other conditions in advanced diabetes and in experimental atherosclerosis in rabbits In suggesting that the arterial lesions found in advanced diabetes are not arteriosclerotic, he attacks the bases on which our knowledge of arterial disease has been constructed and adopts a thesis which no observations published by him or others will adequately support Moreover, he accuses me of calling this lesion 'atherosclerosis' in quotes, as though I had coined a new name for a condition something other than arteriosclerosis It is unnecessary perhaps to restate that the term atherosclerosis is Marchand's (*Verhandl Kong f inn Med Leipzig* 21 23, 1904), that it applies to the important form of arteriosclerosis and that its usage has been accepted universally, even by the opponents of the cholesterol theory of the causation of arteriosclerosis

The positive evidence that disturbances of the cholesterol metabolism are the cause of atherosclerosis can be concisely stated as follows Cholesterol would fulfil all requirements as the etiologic agent if it were a question of a bacterial disease Its constant presence in the lesions of the disease, its isolation from these lesions the reproduction of the lesions in rabbits fed the substance in purity, its constant presence in the lesions of the experimental disease and the failure to reproduce the lesions with any other agent would satisfy the demands for specificity It has been claimed by critics that the rabbit is not a proper animal for atherosclerotic research, since it does not suffer from atherosclerosis naturally This form of reasoning would exclude Banting's experiments on dogs, which gave us insulin, and invalidate most of the animal experimental work with reference to infectious processes It is claimed that the experimental lesions in the rabbit do not always exactly correspond to human lesions To stress the differences and ignore the similarities between the pathology of natural and experimental diseases would be to cast doubt on much of the experimental work on infectious diseases Too meticulous requirements for identity of natural and experimental lesions would be difficult to satisfy in diphtheria bacillary dysentery, cholera, meningococcal meningitis, typhoid and syphilis for example among others There are some differences between the rabbit and human lesions of atherosclerosis The rabbit differs from man anatomically, functionally and posturally The differences in the lesions are for the most part marked by the excessive character of the experimental processes that are rapidly produced by excessive dosage of the substance The closeness of the reproduction of the human lesions in general cannot be denied

I have been able to show that the lesions of human aortic atherosclerosis owe their variety to the relative ability of the cells in these lesions to metabolize cholesterol In youth the power to metabolize cholesterol within phagocytic cells is great and minimal permanent lesions result In the middle period of life this metabolism is slowed and scarring results In old age this metabolism ceases and so-called atheromatous 'abscesses' are the standard lesion (Lear, Timothy Atherosclerosis, the Important Form of Arteriosclerosis, a Metabolic Disease, THE JOURNAL, August 17 p 475)

Finally in no other condition has there been so widespread human experimentation in pathogenesis as was carried out in the feeding of high fat diabetic diets, rich in cholesterol, in the

decade 1920-1930 The results were just as definite as those obtained in the experimental rabbit The relative dosage of cholesterol was smaller than the standard experimental dose in rabbits, and the results were more slowly produced The human lesions, while not as spectacular as the more rapidly produced rabbit lesions, were spectacular enough, particularly in children Moreover, the reverse procedure, i e., the cutting down of the fats in the diet, including cholesterol, resulted in a return to the status quo ante experimentum—absence of xanthomas and of leg artery lesions demonstrable by roentgen examination in children, together with a return to the normal incidence of atherosclerosis

Dr Moschcowitz believes that stresses are the causes of arteriosclerosis It is recognized that stresses are responsible for the selective localization and degree of the lesions Other factors, including particularly aberrations in the function of the thyroid gland, play an important part, but basically atherosclerosis is dependent for its causation on disturbances in the cholesterol metabolism

TIMOTHY LEARY, M.D., Boston

To the Editor—While a letter is too brief a vehicle for the discussion of so disputed a point as the etiology of arteriosclerosis, some statements in the communication of Dr Eli Moschcowitz regarding diabetes and arteriosclerosis call for a reply Few would subscribe to the belief that diabetes mellitus alone is a cause of arteriosclerosis, but the evidence is strong that the metabolic disturbances occurring in the course of diabetes are important factors in the development of arteriosclerosis of the atherosclerotic type

With two statements particularly of Dr Moschcowitz we take issue 1 "To my mind all evidence seems to show that arteriosclerosis is the cause of diabetes rather than the reverse" 2 "When diabetes occurs in arteriosclerosis, the inference is that the capillaries of the islands of Langerhans are affected"

As regards this first point, at least 10 per cent of all cases of diabetes begin in the first two decades of life without any evidence of the existence of arteriosclerosis Indeed, one third of all cases begin before the fortieth year In our experience, diabetic children are not arteriosclerotic at the onset of their disease but may develop arteriosclerosis as the diabetes progresses This development is minimized by adequate control of the diabetes by means of insulin and the avoidance of unbalanced diets high in fat The peak of age incidence of diabetes antedates that of arteriosclerosis The frequency of development of diabetes diminishes after the age of 55 years, although the frequency of arteriosclerosis in the community certainly increases after this age Patients with diabetes of short duration have no more arteriosclerosis than nondiabetic persons of the same age at autopsy But patients with diabetes of long duration show vastly more arteriosclerosis, especially in the hearts and legs, than nondiabetic persons Many cases of diabetes at autopsy show little or no arteriosclerosis of pancreatic vessels, even though vascular damage elsewhere may be severe.

Dr Moschcowitz's second statement is difficult to understand Why depend on inference when direct observation has been made of thousands of islands of Langerhans and their capillaries? More than 20 per cent of diabetic pancreases show no significant pathologic changes (Warren, Shields The Pathology of Diabetes Mellitus, Philadelphia Lea & Febiger, 1930) In many others no vascular changes are seen. Possibly hyalinization of the islands might be interpreted as a vascular lesion, but certainly not as arteriosclerosis

If arteriosclerosis causes diabetes, why is it that after middle life, as the diabetes progresses in duration and the arteriosclerosis increases, the diabetes is so apt to become less severe?

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed Every letter must contain the writer's name and address, but these will be omitted on request

FREQUENCY OF BOWEL ACTION IN INFANTS

To the Editor—Of what sins of omission or commission am I guilty that so many of the babies that I deliver develop at about 1 week of age a very loose bowel? How am I to prevent it and what is a better treatment than protein milk? Please omit name

M.D. Illinois.

ANSWER.—The writer of the question omits to state whether the babies he refers to are breast fed or artificially fed.

Newly born breast fed babies often have numerous and somewhat undigested stools, though they may gain in weight and show no constitutional effects It has been suggested that this frequency of evacuations is due to an increased fermentation of food in the intestinal tract or to an irritation of the mucosa of the large bowel caused by the fermentation products though as a general thing the increased evacuations have no particular significance This group of infants, as a rule, require no medication though if the condition persists unusually long or constitutional symptoms are present a 1 or 2 per cent solution of casein boiled in water will usually diminish the number and cause a firmer consistency of the stool

A similar mild diarrhea may occur in artificially fed infants if however they are restricted to a four hour feeding period and overfeeding is avoided and the food is properly prepared, with avoidance of an excess of sugar, the number of stools should promptly come to be of normal frequency and consistency If the condition persists a 2 per cent solution of powdered casein, boiled in water, may be added to the day's feeding

URTICARIA FROM FURS

To the Editor—A man aged 28 has been having frequent attacks of urticaria for the last four months He handles furs almost daily The first attack occurred October 1 a few hours after a light evening meal consisting of cheese pickles and beer and was characterized by a generalized wheal formation covering the entire body The wheals persisted especially on the lower extremities and were more marked at night From October 1 to 9 the nocturnal outbreak of wheals was only slight and partial relief was obtained by the use of epinephrine on four occasions and gynergen (ergotamine tartrate) for the remainder of the time Urine examination and blood studies including a Wassermann test were negative From October 9 to 14 urticarial attacks were quite severe October 14 he went to Baltimore where skin tests for sensitivity to furs foods and pollens were found to be negative He was started on nonspecific protein injections at that time 10 cc. injections were given at four day intervals for six times with no noticeable effect November 1 he received whole blood injections six 10 cc. injections being given at intervals of five days This treatment yielded favorable results A second series was started January 14 but the attacks again continued mostly on the lower extremities and on two occasions with severe swelling on one side of the head and face He has been on an elimination diet for the past month with no noticeable result The patient is not of an extremely nervous temperament and he leads a rational wholesome life Can you suggest a possible etiology or any further treatment for these allergic attacks? Please omit name.

M.D. West Virginia

ANSWER.—Urticaria is not a clinical entity It may occur as a result of a large variety of sicknesses, such as hypersensitivity (allergy), serum sickness and certain blood dyscrasias.

Urticaria due to allergy may follow the eating of certain foods that contain protein Eggs, wheat, milk, fish, cheese, chocolate, pork, nuts and berries are the most common offenders, other foods may cause attacks of hives at times. In this particular case it might be wise to eliminate the foregoing foods for two or three weeks

Drugs frequently bring on hives and angioneurotic edema, especially the latter The most frequent causes are the coal tar derivatives, especially amidopyrine acetylsalicylic acid, acetanilid and acetphenetidin Quinine is also an important drug in this connection barbitol preparations are likewise frequent offenders and certain other drugs may cause swellings It is best to eliminate all drugs

Urticaria may also come from contact with furs, silk, hairs dyes and other chemicals and plants of various kinds The history of such contact should be searched In this case the fact that the patient works with furs would indicate a possible hypersensitivity either to a fur or to one of the dyes used in treating the furs Paraphenylenediamine has been especially incriminated Contact or patch tests should be done with suspected furs, dyes, chemicals and silks For such tests the

material is moistened and placed against a normal area of skin and held in place by adhesive plaster for from twenty-four to seventy-two hours. Redness with vesiculation constitutes a positive test.

Avoidance of furs for two or three weeks may be advisable. If there is a hair mattress or a feather pillow, it is wise to avoid these for a time, some cases have been cleared up by this means. In all elimination trials (in order to avoid confusion) it is best to try one thing after another, not at the same time.

If no definite cause can be found for the hives, nonspecific treatment should be tried, autohemotherapy may be given again, peptone and vaccines sometimes relieve. Some cases seem to be due to physical allergy (heat, cold, pressure), Duke has written extensively on this subject.

SWIMMING AS A HAZARD TO PERFORATED EAR DRUM

To the Editor—At some period during early childhood following scarlet fever I had an ear complication. Through misunderstanding the condition received no attention until after the drum had spontaneously ruptured. It was then treated vigorously for a long time with no effect so far as the discharge was concerned. Very gradually growing less the discharge finally stopped when I was about 17. Since that time the discharge has occurred intermittently following a cold. The rupture in the drum is permanent. In 1923 following a swim (I had never been advised not to swim) I began to get very dizzy. The dizziness became so pronounced that confinement in bed for a week was necessary in a hospital. It was then discovered that some form of cellular detritus was forming in the attic of the middle ear. This dropped down packed around the oval window and also caused an engorgement of the blood vessels through mechanical pressure. Roentgen examination showed the mastoid to be hard and sclerotic. Search for cholesterol crystals, polypi or granulations was negative. Bacterial cultures were negative. Diagnosis was made of a perilyabyrinthitis. Syringing was done and the detritus removed which resembled pieces of very thin cartilage. The exact nature was never worked out. From this time on there was no trouble until 1927 when there was a recurrence. Since that time I have had trouble several times a year especially this year during which I have had only short periods of comfort since February. My general health is excellent. There are no familial diseases and very few colds. I do a good deal of strenuous athletics. The treatment has not varied since. I am under constant observation and the middle ear cavity is swabbed out occasionally with 1 per cent yellow mercuric oxide. Recently the Elliot heat treatment has been tried within the nose experimentally. The percentage of hearing in the ear is markedly good considering the amount of destruction present consequently it is desired to keep away from radical operations. I have been seen and treated by many high class men. Any possible advice will be deeply appreciated.

M D Virginia

ANSWER—It is always advisable when a perforation of the drum membrane is present to prevent the entrance of cold water into the ear. Therefore, special precaution must be used when taking a shower bath or when swimming, by placing a fairly large piece of cotton, covered with petrolatum on both sides, into the orifice of the external auditory canal and then putting on a tight fitting rubber cap covering the ears. The danger of getting water into the ear is twofold. In the first place a caloric reaction may be caused producing vertigo, so that drowning may occur. Secondly, an acute infection of the ear is often induced. As long as the hearing is fairly good if there is no cholesteatoma formation, together with the absence of headache or vertigo, no radical operation is indicated. If only a small amount of cholesteatoma is present, and it yields to a few irrigations of the attic with 70 per cent alcohol, operation may often be avoided. If some of the other symptoms mentioned such as severe headaches and vertigo, appear, radical mastoidectomy is usually indicated.

CHILBLAINS

To the Editor—Will you kindly inform me as to the methods that work the best in the treatment of chilblains? The patient I have reference to is a man aged 24 in good health. He works at a filling station and has suffered for the past three winters from chilblains which confine themselves to the toes of both feet and become very severe during the night. Please omit name.

M D Minnesota

ANSWER—The predisposition to chilblains is the important thing to combat. This is due to a tendency to acrocyanosis which in turn is due to faulty circulation or faulty nutrition or a combination of the two and even focal infection may have a share in the persistence of the lesions. Hence the patient's general condition and mode of life should receive careful study. Foci of chronic infection that may lower the patient's resistance should be removed. His diet should be complete and adequate with avoidance of excess of carbohydrate, if the patient is lean or of excess of protein if the

patient has a tendency to intestinal putrefaction. The condition of the peripheral circulation requires improvement which might be secured by vigorous movements of the toes for a few minutes several times daily, while holding the foot well elevated.

Prolonged standing in cold and wet as well as sudden warming of the foot after it has become chilled should be avoided. This may be so difficult for the patient under discussion that it might be necessary for him to change his occupation.

The footwear should be warm, loose fitting and kept dry, no garters are permitted. If the patient has a tendency to damp feet the socks should be changed as often as required. At such changing an alcohol rub might be of advantage.

Systemic medicinal treatment might aim at giving restoratives if there is iron vitamin or endocrine (e. g., thyroid) deficiency. Calcium (lactate) might be tried, if no other medicine seems indicated.

If this prophylaxis has failed and chilblains are present, deep vigorous proximal massage of the whole limb with the use of any desired lubricant—the medication probably is unimportant—and with brief, slow, gentle kneading of the affected part is probably the most important item. Immersion in a warm foot bath, followed by a dash of cold water, may well precede the rubbing. Periodic reversal of the galvanic current while the feet are immersed in warm water adds to the value of this exercise to the blood vessels. A cool evaporating compress most especially at bedtime, gives comfort. Extremes of thermic treatment that may result in aggravation of the paretic vasodilatation must be strictly avoided.

HYPOGLYCEMIA

To the Editor—A woman aged 40 of Irish German descent whose weight is 153 pounds (69 Kg.) and whose height is 5 feet 4½ inches (163 cm.) apparently in good health complains of craving for candy and cakes. She will eat a pound of candy or more at a time and half a cake or more. She will hide the sweets and will obtain them in every way possible. All blood and urine examinations give normal results. She has been under treatment in a hospital on a diet but still craves the sugars. She is ashamed of the craving which has been present for a period of ten years. She often tries to break herself of the habit but is unable. Contrary to her previous treatment I advised her after restrictions had failed to have her candy as she wanted it not to sneak it and to feel free at any time to eat as she liked. Can you advise me as to cause, treatment and prognosis?

L E JEWELL MD, Meridian Idaho

ANSWER—Repeated blood sugar determinations at the time of the patient's greatest craving might be worth trying, with a view to determining the existence of a hypoglycemia due to hyperinsulinism. If present, this might account for acute hunger and craving for sweets. In the absence of such manifestations the probability is that the condition rests on a psychologic basis and should be treated as such. The prognosis depends on the obesity that results, namely, an increased susceptibility to diabetes, hypertension and the degenerative diseases.

EXAMINATIONS AND MANIPULATION IN SACRO ILIAC DISEASE

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL* Dec 15 1934 page 1874 under the heading Subluxation of Sacro Iliac Synchondrosis there was a discussion of various methods of examination and of treatment by manipulation of diseases of the sacro iliac joint. Would you be so kind as to define for me the various tests which you note as being recommended by Dr Lewin namely (1) the fabere test (2) the Gaenslen test (3) the Magnuson manipulation and (4) the Cox manipulation.

R I HARRIS MD Toronto

ANSWER—1 The fabere test is sometimes referred to as the Patrick sign. With the patient lying supine, the right heel is placed just above the left patella. The right knee is allowed to drop toward the examining table. It should drop naturally. When the test is positive the right knee is "hung up", then the left heel is placed above the right patella. This test is indicative of a lesion of the hip joint or of its periarticular structures. The word fabere is not a man's name but is a combination of the first or first and second letters of the words flexion, abduction, external, rotation and extension.

2 In the Gaenslen test with the patient's right leg projecting over the side of the examining table the patient grasps his left knee flexing his knee and hip. He thus firmly secures the left half of the pelvis in flexion. The examiner then forces the right leg and thigh in hyperextension over the edge of the table until the limit is reached. This maneuver produces a sort of towel wringing' rotation movement of the pelvis and causes pain in an inflamed sacro iliac joint. The completion of the test is performed with the left leg projecting and hyperextended after the right side has been hyperflexed.

3 In the Magnuson manipulation, under gas anesthesia the patient is placed on his back so that the limb to be manipulated juts out from the side of the examining table. The limb on the affected side is manipulated as in the Baer maneuver and from this position of hyperflexion is suddenly thrust into the position of hyperextension. The second maneuver consists in the surgeon locking his hands under the patient's lumbar spine and exerting a sudden upward pull in order to increase the lumbar lordosis. A tight binder is then applied.

4 The Cox manipulation is performed without anesthesia. The patient lies prone on the floor. He suspends himself on his forearms, holding on to some object, such as a radiator, and is manipulated as follows. The surgeon grasps both ankles, raising the patient's body from the floor. The patient's body is allowed to sag while sharp, sudden traction is applied to the affected leg. Sometimes an assistant makes a thrust on the sacral region.

PHRENECTOMY IN CHILD WITH TUBERCULOSIS

To the Editor—A child aged 6 years at a sanatorium has an adult type of tuberculous lesion in the right lung field. There is a light apical infiltration and a dense basal infiltration with basal cavitation as determined from roentgen examination. Because this type of disease is peculiarly fatal in childhood and because the left lung is practically clear of disease the question of collapse therapy has been considered. Phrenicectomy has been suggested because of the predominantly basal type of lesion but was rejected because of the likelihood of producing severe deformity of the child as it developed. Can you inform me through the columns of THE JOURNAL as to the youngest patient in whom phrenicectomy has been performed? What deformity has been produced by the operation in young patients as they continue to grow? Theoretically is phrenicectomy likely to produce deformity as the child develops? Is phrenicectomy likely to produce greater skeletal deformity as the child grows than would collapse of the lung by artificial pneumothorax? Please omit name.

M D, Massachusetts

ANSWER—In a girl, aged 8 years, who received phrenicectomy, and a girl, aged 6 years, who received pneumothorax, there has been no visible skeletal deformity, the collapse being present two years and one year respectively. The Germans report collapse therapy performed in infants, even with the childhood type of primary infection, claiming thereby to reduce fatalities incident to a generalized military tuberculosis or a tuberculous meningitis. The phrenicectomy per se will not produce deformity. The type of lesion described in the question is always and of itself accompanied by considerable deformity. In the event of natural healing, this deformity will tend to increase as the child grows. Chest changes of a degree dependent on the extent of the lesion will result from the intrathoracic disease. These changes will be retraction of the chest wall, depression of the supraclavicular and infraclavicular fossa, narrowing of the rib interspaces, flaring of the scapulae, atrophic changes in the muscles and, if continued over a long period of years, a scoliosis of the dorsal spine, but collapse therapy when performed in time will tend to limit rather than exaggerate the deformity. The procedure tends toward a prompt suppression of the disease and consequently toward an amelioration of the deformity resultant on the disease. Phrenicectomy is not likely to produce any greater skeletal deformity than would collapse of the lung by artificial pneumothorax. As to the advisability of collapse therapy, it is a known fact that the adult type of pulmonary tuberculosis in children presents a very poor prognosis. Consequently, in estimating the indication, the question of deformity, which anyway is inherent in the lesion itself, has little weight in face of the usual outlook for a rapid spread of the disease and death.

SCLERODERMA

To the Editor—In Queries and Minor Notes I have often noted a great many important problems solved for the general practitioner. I therefore take the liberty of writing you to ask about a case of scleroderma that has come under my care. A woman aged 34 married and the mother of two children has for the past two years had this disease. She has had a thoracic ganglionectomy thyroid therapy ketogenic diet therapy supported by ammonium chloride also massage and diathermy treatments and pancreatic extract therapy (insulin free). All of these without benefit. What is known about parathyroidectomy in this disease and what other means of therapy would you suggest? Please omit name.

M D Florida

ANSWER—The therapy of generalized scleroderma presents great difficulties and, according to the experience of authorities who have written on the subject, there is no specific form of treatment that is available. Improvement has occasionally been reported after the use of thyroid extract and pancreatic extracts, but it has been found by most observers that almost all methods of treatment have been palliative and not curative. There have been a number of reports of pathologic calcification in the skin of patients suffering from scleroderma. In a case reported by

Basch, Leibovici Durupt and M. Basch (*Bull et mem Soc med d hop de Paris* 50 516 [April 2] 1934) a woman, aged 43, presented a clinical picture of scleroderma complicated by patches of calcification in the skin and about the joints. These changes had been preceded by Raynaud's syndrome. Parathyroidectomy was performed in combination with periarterial sympathectomy of the brachial artery. Some improvement in the condition of the skin is reported, which was attributed to the periarterial sympathectomy. There are further papers on this subject by Wessenbach (*Bull Soc franç de dermat et syph* 40 1439 [Feb.] 1934) and by B. Paggi (*Polichimico [sez. chir]* 41 371 [July] 1934).

TREATMENT OF SYPHILIS—BISMUTH GRIP

To the Editor—Last summer I began antisyphilitic treatment of a 4 plus woman aged 33. I gave her five injections of neoarsphenamine, 0.45 Gm. Each injection caused much generalized aching over the body and each successive injection made the aching much worse. She became discouraged and stopped treatment. This winter she returned for further treatment. I began with injections of a bismuth compound in the hip. These caused the same aching only worse. By the time she had the fifth injection she had to go to bed. All joints were swollen and red, and aching was severe. She had to be turned in bed on a sheet for three days. The treatment was stopped and the aching is slowly leaving and the joints are returning to normal. Is this a Herxheimer reaction? How am I going to treat this patient? She received the neoarsphenamine every sixth day and the bismuth compound every fourth day. If you tell me to give less intensive treatment may one expect a cure in the same length of time or does it take longer?

M D Kansas

ANSWER—In the first place, it is difficult to understand what is meant by a "4 plus woman." It would be much more satisfactory in answering this query if more information were available as to the evidence of the syphilis in the patient. Simply a "4 plus woman" means little when one considers the many possibilities, and also the type of laboratory that may have made the reaction. Probably the generalized aching has nothing to do with syphilis, either after the arsenical injections or after the bismuth injections. It certainly is not a Herxheimer reaction.

It is to be recommended that the patient be very carefully examined. If the blood Wassermann really shows a 4 plus reaction, it might be well to do a lumbar puncture as well, and if evidence of syphilis is really found perhaps start her off on a preliminary course of mercury rubs, if she has the symptoms spoken of, giving her 4 Gm of the 50 per cent official ointment as a rub every night, and considering a course of from sixty to eighty rubs as a course of treatment. Perhaps following this one might try the neoarsphenamine again in small doses, using doses, say, of 0.3 Gm every seven days. We would be much interested to learn if the patient has any further reaction. Frankly, we are inclined to feel that there must be some other explanation for these reactions. It is true that there is a condition known as "bismuth grip." The patient, after having had quite a lot of bismuth injections, begins to have vague symptoms of headache, pain in the bones and muscles, and discomfort of that type, which will continue until the bismuth is stopped. Anything of this sort after arsenic, if it occurs at all, is most unusual, and for it to have come on so acutely at the onset of treatment seems out of all reason.

USE OF INTERFEROMETER IN DETERMINING BENZENE FUMES

To the Editor—March 29 you very kindly sent me some reprints from Queries and Minor Notes giving the effects of naphtha and other constituents of lacquers and in one of these it stated that an interferometer should be used to find out the quantitative determination of benzene fumes. Subsequently I wrote asking where one of these could be obtained, whether they had to be bought or whether they could be rented but I heard nothing from you.

GEORGE N. PRATT M D, Nenab Wis.

ANSWER—The best known type of interferometer is the Zeiss, which is listed in the catalogues of the principal laboratory equipment supply houses. The current catalogue of the Arthur H. Thomas Company (West Washington Square, Philadelphia) contains not only a description of this apparatus but a number of citations from the literature as to various fields of its usefulness. In this country the Barrett Company of New York, producers of benzene and other hydrocarbons, have carried out many tests of hydrocarbon concentrations under industrial conditions, using an interferometer. The U. S. Bureau of Standards possesses extensive accumulated data on the use and worth of this instrument.

It should not be understood that this device is either expensive or readily usable. The initial cost of the instrument is in excess of \$500. Thereafter it may become necessary to obtain calibration from time to time to assure reliable results. The

instrument is of restricted value under many industrial circumstances, owing to the fact that benzene, benzene, naphthas toluene and xylene rarely are used as single entities but as mixtures with various esters, acetates alcohols and glycols. This fact precludes any ready standardization of the apparatus to meet the diversity of vapor conditions likely to be encountered.

HEREDITY IN HYDROCEPHALUS

To the Editor—A married woman aged 29 white has had two pregnancies (five years apart) each of which resulted in a child deformed by the presence of meningococles the first time in the cervical the last time in the lumbar region. Hydrocephalus formed in the first and is also present in this last child (now aged 2 months). The woman's past history is essentially negative and physical examination is negative. The Wassermann reaction is negative and the urine normal. However during pregnancy her appetite becomes voracious and she gained between 85 and 100 pounds (38 and 45 Kg) during each pregnancy which weight she subsequently lost during the year following delivery. Her thyroid is enlarged during pregnancy (noticeably) but no other abnormalities can be detected. Her usual weight is 145 pounds (66 Kg) and she is 65 inches (165 cm) tall. Labor is easy. Is it likely that any further pregnancies will result similarly? Any suggestions as to cause and treatment will be appreciated. The husband appears normal and there is no family history of anything similar. If published please omit name.

M D New Jersey

ANSWER—A review of the literature does not prove that there is a distinct hereditary element in spina bifida and hydrocephalus but enough cases are on record to make one believe that a repetition of these abnormalities cannot be denied. There are many cases on record of large families with only one such deformity. The cause of such monstrosities is not known, but defective germ plasma is generally assumed. A diseased endometrium may cause a defective germ plasma and a diagnostic curettage might be helpful therapeutically. The theories that avitaminosis and endocrine abnormalities are causative of monstrosities have little, if any, present support. Since the patient gained such an enormous number of pounds during each pregnancy, the endocrine theory would seem to be a plausible explanation and treatment along the lines of prevention of obesity offers some hope of cure. Our knowledge of the growth hormones of the anterior pituitary body is not sufficiently large to assign to this organ a role in the production of monstrosities.

EPILEPSY AND PREGNANCY

To the Editor—Within the past year I have inherited two petit mal cases. I delivered the first patient aged 19 years of her first baby. She has been treated by neurologists gynecologists and surgeons for the last ten years. They all had held to the possibility of improvement following delivery of a baby. Her history dates back to a fall of some 12 to 15 feet from a swing at which time she was unconscious for ten or fifteen minutes. I can see no improvement since delivery four months ago and subsequent nursing of the baby. Have I done wrong in permitting the mother to nurse the baby? The second patient a woman aged 29 had one pregnancy nine years ago. She has been having seizures for the last nine years. She also has been to several specialists neurologists psychiatrists and gynecologists. Both patients came to my care taking 1½ grains (0.1 Gm) of phenobarbital twice a day and regular cathartics daily. Both patients are discouraged. Is there anything further to offer them? Please omit name.

M D New York.

ANSWER—There is no justification for believing that pregnancy or parturition will cause cessation of epileptic seizures although during pregnancy there is sometimes a temporary improvement, on the other hand the frequency of seizures sometimes becomes greater during pregnancy. There is no reason for assuming that an epileptic woman should not nurse her child. The situation as to prognosis and therapy is not changed by the fact of parturition.

TREATMENT OF KERATOSIS OF LIP

To the Editor—I have under my care a white man aged 38 suffering from keratosis of the upper lip a patch about 1 cm in diameter. This has been present for the past three years with repeated scaling and peeling. It is not disfiguring but is slightly painful. He has tried various treatments including x rays radium and the electric needle but it returns again. The specialist advises surgery but the patient is afraid of scarring and contraction of the lip. Is surgery necessary? Cold cream is as good a treatment for this condition as anything he has tried. What would you suggest? Please omit name.

M D California

ANSWER—No hint is given as to the kind of keratosis meant. If senile keratosis is intended the location and the patient's age make it an unusual case. Senile keratosis will not resist x rays or radium, if correctly applied. Surgical procedures should not be necessary. It would be wise to have a dermatologist see the patient make the diagnosis and direct the treatment.

INDIGESTION WITH NORMAL ACID VALUES

To the Editor—Will you please comment on the following analysis

| Time | Free Acid | Total Acid | Blood | Bile | Mucus | Lactic Acid |
|-------------|-----------|------------|----------|----------|-------|-------------|
| Fasting | Negative | 5 | Negative | Negative | Trace | Negative |
| 20 minutes | 29 | 44 | Trace | Negative | Trace | Negative |
| 40 minutes | 34 | 55 | Trace | Negative | Trace | Negative |
| 60 minutes | 25 | 41 | Trace | Negative | Trace | Negative |
| 80 minutes | 10 | 24 | Trace | Negative | Trace | Negative |
| 100 minutes | Negative | 30 | Trace | Negative | Trace | Negative |

All the man complains of is a lot of gas and a coated tongue. There is no pain in the stomach. Sometimes a few pains occur in the lower part of the abdomen. He had been taking fifteen drops of dilute hydrochloric acid three times a day for two months when this analysis was made. I would appreciate any comment you can make relative to diet or treatment. The patient is 38 years old and is a mine clerk. If published please omit name.

M D Utah

ANSWER—The complaints of coated tongue and "gas" coupled with relatively normal acid values in the stomach are common. The patient should be given the benefit of a thorough investigation, including a cholecystogram, gastro-intestinal roentgenograms and blood, urine and stool analyses. In addition, a careful inquiry should be made into the patient's past history for evidence of acute or chronic infections or ingestion of alcohol. If no organic lesion is found, diet and bowel regulation should control the symptoms. Fatty, greasy, fried and spicy foods, condiments pies pastry, candy, coffee, tea, alcohol tobacco pork, cabbage and apples should be omitted. Foods allowed include eggs (not fried), milk, toast, cooked fruits and vegetables, boiled chicken or beef and broiled lamb chops and cottage cheese. The bowels should be kept moving regularly. The gastric analysis reveals sufficient acid for normal digestive processes and the ingestion of additional hydrochloric acid does not produce extra benefits.

PLUMBISM IN A CHILD

To the Editor—Recently I have become interested in a case of plumbism in a child aged 16 months. The source of the lead was the paint on the crib and play yard. The roentgenogram shows slight deposits of lead in the bones around the elbow knees and ankles. 1 What is the usual procedure of eliminating this lead from the body? 2 What are the probable effects of the lead if it should be left alone entirely? 3 Is the presence of the lead any contraindication to given serum injections such as toxin antitoxin? 4 Will the presence of the lead tend to accentuate any subsequent fever or illness that the child may develop? Please omit name.

M D Massachusetts

ANSWER—1 Removal of lead from the body (or deleading) may be accomplished by inducing an acidosis or an alkalosis, by deprivation of calcium, or by the administration of parathyroid extract.

2 If the lead is left alone it will probably be gradually excreted from the body over a period of time. A child who harbors lead in the bones and who has been symptom free might again show symptoms of lead poisoning during an acute infection.

3 The presence of lead in the bones would be no contraindication for the giving of serum injections.

4 The presence of the lead would not accentuate any subsequent fever or illness that the child might have. However, the illness might cause the reappearance of the symptoms of lead poisoning.

EFFECTS OF KEROSENE ON SCALP

To the Editor—Your answers to the following questions will be greatly appreciated. 1 What will be the effect of the use on the scalp of deodorized kerosene 87 per cent resorcinol 3 per cent and lanum 10 per cent. 2 What will be the effect of the use of the foregoing on the scalp over a long period of time? 3 What will be the effect of kerosene known and designated as water white kerosene if used in the foregoing proportions in place of deodorized kerosene? 4 What will be the effect of kerosene alone on the scalp? 5 In the event that kerosene is rubbed briskly into the scalp if it is confined by the patient wearing a hat immediately after application would this have a tendency to blister the scalp?

V L CHAMBERS M D Huntington W Va

ANSWER—1 The combination of the deodorized kerosene resorcinol and wool fat makes a good scalp stimulant. A few scalps may be irritated by too much of it for the kerosene is quite strong.

2 Used over a long period the tendency of resorcinol to color the hair green must be considered. This can be avoided by the use in place of it of resorcinol mono acetate.

3 Ordinary white kerosene will have the same effect as the deodorized except in respect to odor.

4 Stimulating.

5 Pure kerosene will blister some scalps even though not covered at once. The kerosene had best be diluted.

TREATMENT OF NEUROSIS

To the Editor—I have a middle aged patient who is moderately neurotic. He lives what neurologists term an 'irritated existence' i. e. there are conditions in his life which seem impossible to change and which are more or less of a constant irritation. He is conscious of his own jumpy condition and during business hours for business reasons, he makes an unusual effort to cover up his condition and to be agreeable. At the end of the day he is all in. Is this the proper way to conduct himself in order to get the best results? Please omit name

M D Missouri

ANSWER.—Without more knowledge of the facts it is not possible to give advice of value. The only alternative to the plan now being followed suggested in the question seems to be that the patient should not "cover up" and should be "disagreeable." This certainly does not seem a more "proper way" to get the best results. It may be suggested that when conditions cannot be changed the best method to be followed is to try to find some activity that will furnish compensatory satisfactions for those which are being missed. Much will depend on the nature of the conditions to be faced. On the other hand, it is possible that conditions alleged as cause for the "irritation" are not the real cause but are merely a convenient peg on which to hang the trouble, much as emotional dissatisfaction and conflicts may be diagnosed as irritable heart, dyspepsia or colitis

MORPHINE IN SOLUTION

To the Editor—In the series of articles on 'Therapy of the Cook County Hospital' appearing in THE JOURNAL the following prescription is given in the article on Pain (THE JOURNAL Dec 22 1934 p 1944)

PRESCRIPTION 13—Morphine Sulphate for Injection
 B Dilute hydrochloric acid 0.05 cc
 Morphine hydrochloride 0.10 Gm
 Distilled water q s ad 10.00 cc.

Concerning this I should like to ask 1 How long will such a solution remain stable and potent if used only infrequently? 2 Can the dose of morphine be increased so that 1 cc would equal 0.015 instead of 0.01 Gm? 3 Can atropine (1 cc. $\frac{1}{500}$ grain) be added to the solution? 4 May the sulphate be used instead of the hydrochloride? 5 Can it be sterilized in the ordinary office electrical sterilizer and kept in an insulin bottle?

M D, New York.

ANSWER.—1 Probably for several months

2 Yes

3 Yes, but only if the material is to be used up in a relatively short period as solutions of atropine salts deteriorate fairly rapidly

4 Yes

5 Yes, but excessive heating should be avoided as solutions of morphine are said to decompose rather readily above 60 C

GASTRIC ACIDITY AND ADMINISTRATION OF HYDROCHLORIC ACID

To the Editor—Can you give me information or references regarding the effect on the acid base balance of the body especially the blood of oral administration of hydrochloric acid in large therapeutic doses and excess doses in normal conditions hypo-acidity and hyperacidity? Also do you know of a good standard for children's gastric acidity comparable to that of Vanzant and Alvarez for adults? My rather prolonged search in the literature has thus far been rather fruitless for these two problems and any aid you can give will be most gratefully received.

MARY LOVELESS M D New York.

ANSWER.—The oral administration of hydrochloric acid in any dose causes a lessening in the reserve alkali of the system in a degree proportional to the size of the dose, and this occurs in normal conditions as well as in hypo-acidity and hyperacidity. Knowledge of the gastric contents of infants and children is still rather meager. In infants, Marriott and his co-workers found the acidity to vary between a p_H of 3 and 4, with an average of 3.75

QUININE IN MULTIPLE SCLEROSIS

To the Editor—I note in THE JOURNAL of May 11 an inquiry with regard to multiple sclerosis. You state that quinine hydrochloride should be used in every case. I have been attending a woman who has had multiple sclerosis for several years. I have tried almost everything but the quinine hydrochloride with no improvement. I should like to know your method and the doses that should be given.

L C BARNES, M D Hamburg Ark.

ANSWER.—Quinine hydrochloride is given by mouth, starting with one-half grain (0.03 Gm) three times daily for one week, then three-fourths grain (0.05 Gm) three times daily for the second week, 1 grain (0.065 Gm) three times daily for the third and fourth weeks and finally 1½ grains (0.1 Gm) three times daily for at least six months. Fluids should be pushed to the maximum at all times

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND STYHILOLOGY Written examination for Group B applicants will be held in various cities throughout the country, March 14. Oral examination for Group A and B applicants will be held in Kansas City Mo. May 11-12. Applications for written examination should be filed with the secretary before Jan. 15. Sec. Dr. C. Guy Lane 416 Marlboro St. Boston

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, Dec. 7. Sec., Dr. Paul Titus 1015 Highland Bldg., Pittsburgh (6)

AMERICAN BOARD OF OPHTHALMOLOGY St. Louis Nov 18. Asst. Sec., Dr. Thomas D. Allen 122 S. Michigan Ave., Chicago

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St. Louis Jan. Sec., Dr. Fremont A. Chandler 180 N. Michigan Ave. Chicago

Book Notices

Obstetrics for the General Practitioner By J P Greenhill B S M D F.A.C.S. Professor of Gynecology Loyola University School of Medicine Chicago. National Medical Monographs. Edited by Morris Fishbein M.D. Cloth Price \$4. Pp 304 with 39 illustrations. New York National Medical Book Company Inc. Doubleday Doran & Co Inc 1935.

The author has developed a small book on obstetrics for the general practitioner. It is brief but not in compendium or notebook style. The book is divided into twenty chapters, which are in logical sequence. For ready reference each chapter in turn is broken up by the conventional headings of etiology, pathology, symptoms, diagnosis, prognosis and treatment. This orderly arrangement contributes materially to the usefulness of the work. There is an especially well chosen group of illustrations, lent by Dr J B De Lee from his textbook.

The chapter on the management of labor is one of the most practical, the one on hydatidiform mole and chorionepithelioma is completely covered from a scientific standpoint but with brevity and clarity, the chapter on placenta praevia is particularly well written and an excellent guide in this dangerous situation.

Greenhill must have debated long with himself before deciding to include a chapter and numerous illustrations on the technic of various methods of cesarean section. He does so "because in many small communities the general practitioner or general surgeon must perform these operations." This is a concession to bad obstetric practice which might better have been omitted in these days of good roads and generally good transportation facilities. Cesarean section is distinctly not an operation for general practitioners or general surgeons, as its high mortality rate attests. The space might profitably be devoted to somewhat more instruction to the general practitioner on the early recognition of conditions often requiring cesarean section.

The chapter on puerperal infection is an excellent one, although containing scarcely enough emphasis on the methods of its prevention and the responsibility of the attending physician in this. Nevertheless, this all appears in the earlier chapter on the management of labor, if the practitioner will read these two chapters together.

The sections on antepartum care and the management of labor occupy only twenty-three pages and include the only discussions on contracted pelvis, postpartum hemorrhage, and asphyxia of the new-born. By contrast, seven pages are devoted to the etiology of abortion and miscarriage, nine pages to polyhydramnios, and slightly more than one page to oligohydramnios. Ten pages are given to syphilis, but gonorrhea is not mentioned specifically. The care of the new-born is mentioned only incidentally. Uterine inertia and hydrocephalus do not appear in the index. Four pages are devoted to the

dystrophia dystocia syndrome and sixteen to local anesthesia in obstetrics, which is recommended throughout the work whenever anesthesia is required. There is no detailed discussion of other anesthetic agents, and analgesia is covered in a sketchy fashion.

The methods of treatment and procedure that are advocated are eminently sound, but it requires knowledge and insight to interpret the directions given. Frequent auscultation of the fetal heart tones is recommended strongly but there is no statement concerning the interpretation of variations in their rate and rhythm. Episiotomy is well discussed and illustrated, but perineal lacerations, even those involving the rectal sphincter, are omitted except for a statement that they should be repaired if the patient's condition permits.

The book is of a convenient size, attractively bound in red and gold, and well printed. With its appearance, and the wise counsel within its pages, it should be a valuable addition to the library of all general practitioners doing obstetric work.

Über die primären Tumoren des Sehnervens und der Sehnervenkreuzung. Inaugural-Dissertation Von Åke Lundberg Med Lic. Paper. Pp 164, with 28 illustrations. Stockholm. Nordiska Bokhandeln 1935.

In this monograph the nature of optic nerve tumors is considered in the light of observations obtained by modern neurohistologic methods. The author studied material from ten cases and in view of the probable embryologic origin of many of these tumors a study of the embryology of the optic nerves was included. In his review of the literature proper credit is given to the important works of Hudson (1912) and of Verhoeff (1922). These authors had decided that most tumors of the nerve itself should be classified as gliomas. The use of modern methods of study may be said to begin with del Rio-Hortega, who found that most optic nerve tumors were oligodendrocytomas. A table of all cases reported since the work of Hudson is included (114 cases). In studying his material the author employed besides the usual stains Holzer's glia stain and Fincher's modification of the Hortega silver and gold impregnation method. The author's ten cases included five tumors of the intra-orbital portion of the optic nerve, two of the intracranial portion and three involving the intracranial portion and optic chiasm. In two cases only postmortem (museum) material was available without a clinical history. In six cases the material was obtained at operation and in two post mortem. The five cases involving the orbital portion of the nerve showed certain similarities in their clinical course. All were in children from 3½ to 10 years of age. In all the principal symptom was unilateral exophthalmos with optic atrophy, which in some cases was simple and in others accompanied by papilledema. All were removed successfully and showed no recurrence after a period of from one to seventeen years. This was in spite of the fact that three tumors could not be removed completely on account of extension through the optic foramen. In two of these cases such extension could be diagnosed preoperatively by roentgenograms showing enlargement of the optic foramen. This relatively benign nature of optic nerve tumors has been noted by other observers, especially Hudson.

The review of published cases involving the intracranial portion of the nerves and chiasm with his own cases is of importance not only to the ophthalmologist but to the neurologist and neurologic surgeon. Such cases are seldom accompanied by exophthalmos and in many cases loss of vision with field changes is the only sign available for diagnosis. Differential diagnosis from other conditions causing optic atrophy is sometimes difficult and the author believes that a number of cases of unexplained blindness are due to such tumors. All his cases but one proved on histologic examination to be gliomas of the type of oligodendrocytoma. In some material a number of astrocytes was found. One case of meningioma involved the intracranial portion of the optic nerve in front of the chiasm. Meningiomas of the intracranial portion must arise in this region tumors behind this point being of necessity gliomas. From his own and other published data in which material was available since the report of Hudson, the author found that seventy-five tumors were gliomas, twenty-nine meningiomas and nineteen of uncertain nature. A characteristic difference between the gliomas and the meningiomas was the age of incidence. Most gliomas involved children, the average age at

time of operation being 12 years, while meningiomas affected older persons, the average age being 25 years. The gliomas involving the nerve always cause loss of vision before exophthalmos is noted, whereas the opposite is the case with meningiomas of the orbital portion. In the case of small children the loss of vision often passes unperceived until exophthalmos occurs. In diagnosis the roentgenograms were only occasionally of value. Intracranial extension of an intra-orbital tumor could sometimes be diagnosed by enlargement of the optic foramen, and in tumors of the intracranial portion erosion of the anterior clinoid processes and undermining of the roof of the optic foramen were sometimes observed as well as calcium shadows in the tumor.

Many other points of interest in this group of conditions are included in the monograph, which presents the most complete review of its subject that has so far appeared.

The Determination and Control of Industrial Dust. By J. J. Bloom, field Sanitary Engineer U. S. Public Health Service and J. M. DallaValle, Assistant Sanitary Engineer U. S. Public Health Service. Prepared by direction of the Surgeon General, United States Treasury Department, Public Health Service. *Public Health Bulletin No. 217.* Paper. Price 15 cents. Pp. 107 with 77 illustrations. Washington: D. C. Supt. of Doc. Government Printing Office, 1935.

At present the workmen employed in the dusty trades form the largest group exposed to any one industrial hazard—a hazard with high morbidity and mortality rates from respiratory diseases as well as systemic poisoning in the case of toxic dusts. The composition, quantity and particle size are the properties producing definite damage. The present bulletin gives the methods and instruments now used for dust studies, the interpreting of results, and their practical applications, especially in regard to control. The volume is meant as a guide to engineers, chemists and others interested in minimizing dust hazards to health. Of the five instruments of choice, that developed largely by the Public Health Service (1922) known as the Greenburg-Smith impinger is recommended as the most adaptable for all around dust determinations, although each of the others has its special field. Probably the bulletin was already in press before a description of the "hot wire" method of Greene was published in England (1934), the inventor of which claims that it is of far greater accuracy. After discussing "the quantification" of dusts, i. e., the determination of quantities present by use of the various instruments, the bulletin details their character and composition, petrographic and chemical examinations, and the application to practical problems. The last six of the twelve chapters concern methods of dust control, principally from the plant engineering standpoint, with various formulas and charts for measuring adequacy, although the last chapter devotes eight pages to personal respiratory protection (respirators, masks and helmets). There is an accompanying bibliography. This whole question is at present in a condition of flux, so that little can be accepted as definitely settled except that there is some definite relation between some inhaled dusts and disease, but studies like the present one are certainly showing the way out, and the authors as well as the Public Health Service are to be complimented on a fine contribution and encouraged to go on.

La maladie des pêcheurs d'éponges nus. Par Skévos Zervos. [Extrait de *Paris médical* No du 4 août 1934.] Cloth. Pp. 29 with 10 illustrations. Paris: Librairie J. B. Baillière et fils. [n. d.]

For many years the sponge fishermen of the island of Calymnos (in Grecian waters) who search for sponges off the islands of Crete and Chypre and in the African seas, have lived in dread of a strange disease, which seemed to attack only them or their fellowmen who worked with fresh sponges. The disease first manifests itself by a sharp stinging pain at almost any portion of the body, but chiefly on the anterior regions. Quickly this initial spot becomes red and swollen and within a few hours may change from red to purple or almost black. Within a short time systemic involvement arises, characterized by headache, nausea, intense fever and chills, sometimes lasting for several days or weeks. The pain is usually general and is most intense about the open wound, which is slow to heal, is prone to necrose, and may eventuate in an abscess. Always healing is slow and painful. Attacks of this character again and again have been the lot of these sponge fishermen. While death is only occasional, the intensity of the pain is such as to make the fishermen continually apprehensive as they go about their work.

This publication is the story of Skévos Zervos's study of this occupational disease. First in 1903 he presented its description to the second Panhellenic Congress, and again in Paris at the Academy of Medicine. In the ensuing years Dr Zervos has established many unusual features of the nature of the disease and its control. The cause was found to be an animal parasite, the "actinion," belonging to the Zoanthes, and homologous to the Actinidea. The parasite is approximately 4 or 5 cm in length. Two rows of minute fingerlike projections occasion the name "actinion," which signifies "ray" formation. The parasite lives attached to the roots of the sponges at the bottom of the sea. As the sponge fisherman uproots the sponges and fills the net bag hung around his neck in front of his body, the disturbed actinion discharges from its mouth its venomous material, which is described as "white, of viscom consistency, like half-dried nasal secretion." The actuality of poison within the parasites is attested by the use of dried actinions by these fishermen for killing off undesirable animals, such as rabid dogs. Dr Zervos describes various types of treatment, such as "cupping" the fresh wound and the application of liquid ammonia. It seems somewhat bizarre that with so large a parasite the fishermen should not long ago have determined the cause of the malady. Whatever may have been their extent of knowledge, much has been accomplished by Dr Zervos in protecting them. Through education, improved therapeutic measures, prevention of infection and careful supervision of the sanitation of boats and docks, this disease never direful, has been brought under control. In gratitude the population has termed its occupational disease the "malady of Skévos Zervos." The author in turn has dedicated his small book to his dear compatriots who have had this disease by the thousand. The challenge of interest is a desideratum of any publication. At every turn this little book extends that challenge. Apparently a remotely situated physician found an unknown disease, he determined the cause, classified the parasite, established the manifestations, created a suitable treatment, and banished the fears of an apprehensive population. Written in a simple, naive style, it contributes its own small bit to the solution of occupational disease problems.

Text Book of Urology for Students and Practitioners. By Daniel N. Flisendrach, M.D., Consulting Urologist to the American Hospital, Paris, France and Harry C. Roitnick, M.D., Clinical Professor of Genito-Urinary Diseases, Loyola University Medical School, Chicago. Third edition. Cloth. Price \$10. Pp. 942 with 711 illustrations. Philadelphia and London: J. B. Lippincott Company, 1934.

This work has had considerable success among students of medicine and busy practitioners. The authors themselves state that their work was written primarily to fulfil the definite need for such a textbook, which would present the whole subject of urology in "the simplest possible manner" to "meet the needs of beginners." This laudable ambition has been accomplished in an admirable manner. One hundred and sixty-two pages are devoted to elementary subjects relative to genito-urinary diseases, 100 pages to the venereal diseases, and the remaining pages to diseases of the genital organs, bladder, ureters and kidneys and to urologic surgery. Diseases of the male genitalia, not infrequently slighted in the past, are covered in a thorough manner. The chapters on venereal diseases are complete and of value to both students and practitioners.

Every effort has been made to facilitate and render quick and sure the teaching of urology. Seven hundred black and white and eleven colored illustrations, many schematic drawings, tables for differential diagnosis, and pictures of operations, step by step, all impress the mind quickly and deeply.

The use of black letter emphasis to the paragraph headings and to important matters may be helpful to some but is confusing and obstructive to smooth, easy reading.

Three new pages on intravenous urography have been added to the chapter on radiography and eight pages on electroresection of the prostate. Otherwise the book shows little change from previous editions. The illustrations are on the whole good and have been drawn from a large number of sources. The style is more that of a compend or outline of urology, presenting the main facts as briefly as possible.

For the student this book has a definite value, and teachers may recommend it with safety and assurance. For the advanced urologist or the research worker or for purposes of reference it is not so useful. However, it fulfils a distinct need.

Nutrition Work with Children By Lydia J Roberts Professor and Chairman of the Department of Home Economics The University of Chicago Second edition Cloth Price \$4 Pp 639 with 18 illustrations. Chicago The University of Chicago Press 1935

Nine years has elapsed since the first edition of this book became available. During that time notable advances have been made in many different aspects of the subject. There have been extended and detailed studies of the growth and development of children. New types of foods have been prepared especially applicable to the child's needs. The Conference on Child Health held in 1930 brought together a considerable number of specialists who by the exchange of their views consolidated opinion on many debatable topics. The new advances have been given careful consideration in the revision of this book, which now constitutes the most extensive and perhaps the best available book on this special subject. The volume begins with an introduction showing the needs for nutrition work, then come definitions of terms and methods of judging nutrition, and analyses of the various studies that have been made of growth at different times and seasons. The causes and effects of malnutrition are considered as well as its prevention and treatment. Then come the constructive features of the volume, which describe the nutrition program in the school, the teaching of nutrition at various grades and other aspects of nutritional work in schools as well as that carried on by special agencies. Each of the chapters is supplemented by a bibliography and there is a fine collection of references to health materials for use in teaching. The index is adequate and indicates the greatly enlarged scope of this work.

Socialization of Medicine Compiled by Julia E Johnsen The Reference Shelf Volume V Number 5 Cloth Price 90 cents Pp 335 New York H W Wilson Company 1935

The H W Wilson Company has for some years prepared under the general title "The Reference Shelf" a series of reference and guide books for debaters on various topics. The present volume on socialized medicine provides two excellent briefs for the affirmative and negative sides of the subject, a fairly extensive but well selected bibliography, definitions to guide debaters in their understanding of the topic to be discussed and then a number of reprints of various articles by physicians, social workers and economists on this subject. These articles are divided into general discussions, affirmative discussion and negative references. It is exceedingly interesting to find the names of John A Kingsbury and Rufus Rorem among those whose articles are put on the negative side. What a gnashing of teeth there will be when these gentlemen find where they have been located! Presumably Mr Kingsbury was put into the negative side because he says he does not advocate the socialization of medicine but the socialization of the payment of medical costs. This would seem to be largely a distinction without a difference.

Maladies de l'intestin III Cancer du rectum (diagnostic traitement chirurgical radiumthérapie soins médicaux) lymphosarcome tumeurs villoses polype solitaire polypose rectocolique fibromes myomes angiomes Par R Bensaude Avec la collaboration de J Charrier chirurgien des hôpitaux et al Paper Price 60 francs Pp 367 with 127 illustrations Paris Masson & Cie 1935

The diagnosis, surgical and radium therapy, and medical management of the significant neoplasms of the rectum and sigmoid colon are discussed in this volume. Bensaude stresses the dictum that cancer of the rectum when uncomplicated does not ordinarily produce cachexia. Particular emphasis is given to the importance of diagnostic proctoscopy. Digital examination is hardly mentioned. The introduction of proctoscopy is attributed to a Parisian surgeon Desormeaux and the German Kussmaul and others who utilized his method are accused of omitting reference to him. Differential diagnosis is treated extensively. Surgical extirpation is the method of choice for carcinoma. Radium is resorted to only in diffuse growths beyond surgical aid. Abdominal perineal and abdominoperineal methods of approach for resection of the rectum and the terminal sigmoid are described. In 40 per cent of operated cases, no recurrence appeared after three years and longer.

A number of cases of rectocolic polyposis displayed clubbed fingers, and this sign is suggested as a diagnostic aid. Colonic polyposis is also associated occasionally with infantilism.

The print is large and readable. The paper and the many illustrations are good. The tests, written by several authors, are uniformly clear and precise. However, an index is lacking and the bibliography is inadequate. The volume is recommended to surgeon, proctologist and internist.

The Principles and Practice of Surgical Nursing By Charles D Lockwood A B M.D. F.A.C.S. and John A Wolfer M.D. F.A.C.S. Associate Professor of Surgery Northwestern University Medical School In collaboration with Mildred E Newton B.S. R.N. Instructor and Supervisor of Medical Nursing Division of Nursing University of California Second edition Cloth Price \$2.75 Pp 371 with 172 illustrations New York The Macmillan Company 1935

The second edition of "The Principles and Practice of Surgical Nursing" has been revised and rewritten by Dr Wolfer and his collaborator Miss Mildred E Newton. The first edition was the work of the late Dr Charles D Lockwood. The monograph is essentially an outline of surgical practice and is similar in many respects to the compends which are found in the hands of senior medical students just before examination time. The book is well written and well illustrated. The subject matter is presented in a simple, direct manner. The authors deserve credit for the care which they have exercised in confining the text to important headings and in avoiding the confusion that commonly arises from attempts to incorporate too much theory or too many disputatious details. The chapter on inflammation has been supplemented and placed at the beginning of the text, and the chapter on the treatment of burns has been rewritten to accord with the present day practices.

It would seem that the most cogent criticism of the book is to be found in the choice of its title. It contains little of the essential principles and practice of surgical nursing but deals almost exclusively with the principles and practice of surgery. It should be received gratefully by instructors who are in search of a clear, concise textbook of surgery for nurses.

Reports of the Committee upon the Physiology of Vision XIV Characteristics of Dichromatic Vision with an Appendix on Anomalous Trichromatic Vision By F H G Pitt Medical Research Council Special Report Series No 200 Paper Price 1s 3d Pp 58 with 20 illustrations London His Majesty's Stationery Office 1935

This report is a rather technical description of investigations of color vision made with the Wright colorimeter. This is a color mixing apparatus by which, as in the Nagel anomaloscope, pure colors are matched by mixtures of their complementary colors. In a series of normal and partially color-blind dichromatic observers, data concerning the discrimination of color luminosity and hue were collected. The report should be read in the original by those interested in color vision.

Handbook of Tuberculosis Schemes for Great Britain and Ireland Eighth edition Paper Price 5/- Pp 169 London National Association for the Prevention of Tuberculosis 1935

This directory of tuberculosis schemes in Great Britain and Ireland is of interest to American physicians mainly in that it indicates the close tie-up in the United Kingdom between preventive and therapeutic phases of the fight against tuberculosis, and also between governmental and voluntary agencies. Rough comparisons may also be made, so far as international comparisons have validity, between provisions for the tuberculosis in the British Isles as compared with similar provisions in this country. In view of the numerous dispensaries and clinics available, even in counties with comparatively favorable tuberculosis death rates, there would seem to be little left for the private practitioner to do as far as tuberculosis is concerned.

The Economic Outlook in Higher Education for 1934-35 By Henry G Badger Assistant Statistician Office of Education United States Department of the Interior Office of Education Pamphlet No 58 Paper Price 5 cents Pp 49 Washington D C Supt of Doc Government Printing Office 1934

This pamphlet is a review of the economic and financial outlook among institutions of higher education for 1934-1935 as seen by the financial officers of those institutions. It appears that for the group studied, the decrease in income which has prevailed for the past two years is about at an end. The reports available from some 500 institutions (53 per cent of those to which inquiries were addressed) would seem to forecast a change of less than 1 per cent from the previous year in expected current and capital receipts, in budgeted expenditures for educational and general purposes, and in the number of staff members or in their compensation.

Medicolegal

Malpractice Medical Books as Evidence, Expert Testimony—The plaintiff suffered a fracture dislocation at the left ankle joint, a so-called Pott's fracture. The physician-defendant treated the injury. His patient was dissatisfied with the result and later was treated by other physicians. She sued the physician who treated her in the first instance. From a judgment in her favor, he appealed to the Supreme Court of Iowa.

The physician-defendant took exception to a ruling of the trial court that permitted the use of medical books when he was under cross-examination. He had not testified that he had examined medical books or that he relied on medical books in general or on any particular book, but on cross-examination he was asked whether he had consulted certain books and how many of those books advised a certain method of treatment. His counsel objected, but the trial court overruled the objection and required the defendant to answer. The Supreme Court held, however, that the trial court erred. It is not competent on cross-examination, said the Supreme Court, for a physician testifying as an expert to go into the contents of medical books when he has not referred to any book or named any book as an authority or one on which he relied. This rule is founded on the fact that the books themselves are not admissible. In this case such cross-examination was inadmissible for the further reason that the witness was asked to give a summary of what certain books taught on a subject, and if the books themselves were not admissible then such a summary likewise was not admissible.

It is error to admit medical books in evidence, the court pointed out, and where plaintiff's counsel in a case read a long extract from a medical book and asked a witness if he had ever read it, the error was not cured by the trial court sustaining an objection to the question, the objectionable matter had been read and could not be eliminated by a ruling sustaining an objection to it. *Etzkorn v City of Oelwein* 142 Iowa 107, 120 N W 636. The Supreme Court, quoting *Birby v Railway & Bridge Co.*, 105 Iowa 293, 75 N W 182, pointed out that data of medicine are constantly shifting with new discoveries and that conclusions which may be considered sound today are repudiated tomorrow, saying—

A medical work may be standard this year and obsolete next. The opinion of the same author changes in the different editions owing to new discoveries and a better understanding of symptoms. The very best works aside from observations are largely made up of the opinions either of the author or of others compiled. It is a well known fact that physicians after research and investigation often differ radically.

The only circumstances under which medical books can be read in evidence is when the witness has based his opinion on them and has referred to them as authorities, and this rule cannot be evaded on cross-examination. *Hall v Murdock* 114 Mich 233, 72 N W 150. This rule is based on the fact that the use of books is an attempt "to discredit the testimony of the witness by 'hearsay testimony of the written or spoken opinion of other persons, whom the jury have no means of examining as to their learning, their honesty, or their sources of special knowledge,' which attempt can be justified on neither principle nor difficulty of cross-examination."

The physician defendant, while testifying on his own behalf, was questioned by his own counsel concerning the usual and ordinary practice of physicians and surgeons in the community in which he treated the plaintiff and in similar communities, at that time, but objections on behalf of the plaintiff were sustained and the defendant was denied the opportunity of stating his opinion concerning the matter. The questions asked, said the Supreme Court, were certainly proper and the trial court erred in sustaining objections to them. It made no difference that the witness was the very physician whose conduct was under investigation. His testimony was admissible, its weight was for determination by the jury.

A medical witness for the plaintiff testified that he had had a hundred cases of Pott's fracture previous to the plaintiff's case. He was then asked "In how many of those did you fail to get reasonably good results?" He was asked also "Well,

have you had any case where the reduction and operation—the reduction of the fracture or operation has not been reasonably satisfactory?" Objections to both of these questions, on the ground that they were immaterial and irrelevant, were overruled by the trial court, but, said the Supreme Court, the answers admitted were certainly immaterial. The cases the plaintiff's witness had had and his experiences as to results in other cases were not criteria in this case. The evidence showed that the kind of injury under consideration was quite liable, even with the best of treatment, to give unsatisfactory results. The question had no bearing on the question of negligence or lack of skill of the defendant.

The trial court erred, the Supreme Court said, in refusing to instruct the jury with respect to hypothetical questions, on the motion of the physician defendant, that "you must determine if all of the facts assumed in the hypothetical question are established by the evidence, and if they are, you may give the answer of the witness to such questions such weight as you may deem it entitled to, but if you find that any fact assumed in any hypothetical question has not been established by the evidence, then you will give no weight or consideration to the answer of the expert to such question." The instruction requested was proper. A jury should be given some rule by which to determine the weight to be given to expert opinion testimony. If the facts stated in the question are not correct or true, it destroys the value of the answer, at least to some extent.

The judgment of the court below was reversed and the cause remanded for a new trial—*Wilcox v Crumpton (Iowa)*, 238 N W 704.

Silicosis Liability of Employer Under Common Law—The plaintiff, an employee of the defendant-company, developed silicosis through the inhalation of dust and other impurities in the defendant's factory. He claimed compensation under the workmen's compensation act of New York, but his claim was dismissed by the industrial board. Thereupon he sued the defendant at common law. He alleged that his exposure to dust and other impurities, which had resulted in the disease from which he suffered, was due to the defendant's failure to exercise reasonable care and to perform its statutory duties in the operation of its factory. The supreme court, appellate division, fourth department, denied the defendant's motion to dismiss the complaint and, on the defendant's appeal, certified to the Court of Appeals of New York the question whether the complaint stated facts sufficient to constitute a cause of action.

The employee's suit was based on the theory that, if silicosis was not an injury compensable under the workmen's compensation act, he had a right to recover damages from his employer in an action at common law. His employer contended that, if an employee ever had had any such right under the common law, it had been abolished by the passage of the workmen's compensation act.

It is true, said the Court of Appeals, that for an "injury" within the meaning of the workmen's compensation act no right of action at common law by an employee against his employer survived the passage of the act. The act, however, defines "injury" as meaning only accidental injuries arising out of and in the course of employment and such disease or infection as may naturally result therefrom and certain occupational diseases named in the act. Silicosis, said the court, is not an accidental personal injury within the meaning of the workmen's compensation act for the inception of the disease cannot be assigned to a determinate or single act, identifiable in space or time, or to "something catastrophic or extraordinary." Silicosis is an occupational disease, it is true, the natural and unavoidable result of conditions of employment, but it is not one of the occupational diseases named in the workmen's compensation act as compensable.

The workmen's compensation act provides that the liability of an employer prescribed by the act shall be exclusive and in place of any other liability whatever to an employee or any one else, entitled to recover damages at common law or otherwise, but this exemption relates only to liability for injuries, including occupational diseases, covered by the act, and silicosis is not so covered. There is still a field, said the court, in which an injured employee may seek damages by action at

common law, when there has been fault on the part of the employer. Accordingly, the Court of Appeals affirmed the order of the court below denying the defendant-employer's motion to dismiss the complaint filed by its employee. The court held that that complaint stated facts sufficient to constitute a cause of action—*Barrencotto v Cocker Saw Co, Inc (N Y)*, 194 N E 61.

Malpractice Indemnity Insurance, Insurer Required to Pay Insured Physician's Traveling Expenses Incident to His Attendance at Trial—The Medical Protective Company issued to a physician an insurance policy in which it agreed to defend him at its own expense against any claim or suit for damages arising from malpractice, error or mistake in the practice of his profession. In applying for the policy, however, the physician agreed to attend, assist and cooperate in the preparation and defense of any claim or suit against him, "without charge to the company."

A malpractice suit against the insured physician was instituted at Akron, Ohio, by one Estella Light, as administratrix, and was set for trial, May 23. Counsel for the insurer notified the insured physician, who was then residing in Longview, Texas, to be present on that date and that it would be well for his wife also to be present, and added

You understand of course that the policy we issued to you obligates you to attend the trial of any case at your own expense. We mention this at this time so there may be no misunderstanding in the matter.

The insured physician did not appear at the trial, and, at the request of counsel for the insurer, the case was continued to October 26.

Counsel for the insurer again notified the insured physician of the date set for trial and requested his attendance. The insured physician thereupon replied that his financial condition made it impossible for him and his wife to be in Akron on the date named. He asked that the case be postponed for from three to six months, when he would be in Akron and would be glad to assist and cooperate with counsel. When the case came up for trial October 26, counsel for the insurer moved for a further continuance, stating that the defendant the insured physician, had informed him that it would be impossible for him to appear, but counsel for the insurer did not inform either the court or the plaintiff of the reason given by the defendant for his inability to be present. The court refused to grant a continuance and counsel for the insurer thereupon withdrew from the defense of the insured physician. Judgment was entered against the physician, in favor of the plaintiff, the administratrix of his deceased patient.

The administratrix of the deceased patient thereafter instituted the present proceeding against the Medical Protective Company, as the insurer which had agreed to indemnify the absent physician-defendant against loss resulting from claims or suits based on malpractice. She asked that the judgment against the absent physician be satisfied from the insurance money that the insurer had agreed to pay. The insurer defended on the ground that the insured physician had committed a breach of his contract by failing to attend the trial and to cooperate with the insurer. It claimed that because of that breach it was under no obligation to pay a judgment against him. But the trial court gave judgment against the insurer, which thereupon appealed to the court of appeals of Ohio Summit county.

The failure of the insured physician to come from Longview, Texas, to Akron, Ohio, to attend the trial of the suit against him, said the court of appeals, and his failure to bring his wife with him at his own expense, did not constitute a breach of the condition contained in the physician's application for insurance. Construing the application and the policy as a whole, they meant, in the judgment of the court, that the physician would make no professional charge for attendance at the trial, but they did not mean that he would undertake to travel a great distance at his own expense in order to attend a trial. Under no possible construction of the application and the policy did the insured physician undertake to bring his wife to a trial, when bringing her entailed a large expense and the insurer had indicated in advance that it would not meet such expense.

When the insured physician notified his insurer that it was a financial impossibility for him to attend the trial at his own expense it was the duty of the insurer, under the provisions of the policy to defray that expense. Furthermore, it was the duty of counsel for the insurer, when the case was called for trial to inform the court not only of the insured defendant's inability to be present but also of the reason for that inability as stated by him. It was the duty of the insurer, too, to inform counsel for the plaintiff in the malpractice case of the reason assigned by the insured for his absence, because plaintiff then would have had an opportunity to assist the insured physician in attending the trial. Failure of the insurer to notify either the court or counsel for the plaintiff in the malpractice case of the reason for the absence of the insured physician estopped the insurer from asserting in its own defense a breach of the condition on the part of the insured.

Judgment against the defendant insurer was affirmed.—*Medical Protective Co v Light (Ohio)*, 194 N E 446.

Practice of Medicine License Not Revocable for Unauthorized Acts of Unlicensed Assistant—The fact that an unlicensed person, employed by a physician to assist him by rendering services that do not constitute the practice of medicine, voluntarily and without the knowledge of his employer goes beyond his proper duties and performs acts prohibited by the statute regulating such practice, does not furnish lawful ground for the revocation of the employing physician's license. A rule to the contrary, said the district court of appeal, fourth district, California, would place in jeopardy the licenses of the most conscientious ethical members of the profession, since it would impose on them liability for unauthorized voluntary and furtive acts of their employees—*Barrett v Board of Osteopathic Examiners of California (Calif)*, 40 P (2d) 923.

Medical Practice Acts Conviction of Crime Involving Moral Turpitude as Ground for Revocation of License—The appellee Porter R. Rodgers, a licensed physician, pleaded guilty in the district court of the United States for the western division of the eastern district of Arkansas to a charge of possessing counterfeit money. He was sentenced to serve three years in the United States reformatory. The execution of the sentence was suspended, first for a period of two weeks, then for approximately three and one-half months and finally for a period of five years. While the execution of the sentence was thus suspended, the state medical board of Arkansas revoked Rodgers' license, under a complaint charging him with conviction of a crime involving moral turpitude. The chancery court set aside the revocation order and the board appealed to the Supreme Court of Arkansas.

"Moral turpitude," said the court, is a well defined and easily understood term. In *Fort v Brinkley*, 87 Ark. 400, 112 S W 1084, the court said

Moral turpitude refers to an act of baseness, villainy or depravity in the private and social duties which a man owes to his fellow men or to society in general but not to such acts as are not of themselves immoral but whose illegality lies in the fact of their being positively prohibited.

Webster defines the term as follows

The quality of a crime involving grave infringement of the moral sentiment of the community as distinguished from statutory mala prohibita.

In view of these definitions, the court had no hesitancy in holding that the crime to the commission of which Rodgers pleaded guilty was a crime involving moral turpitude. Possession of counterfeit money, said the court, with intent to corrupt the currency of the country and with intent to cheat and defraud any person to whom it is uttered is a base and infamous crime.

But although Rodgers had pleaded guilty to a crime involving moral turpitude and been sentenced to serve three years in the reformatory, in the opinion of the Supreme Court of Arkansas, he had not been "convicted" within the meaning of the medical practice act. No final judgment had been entered, because the sentence had been suspended, and Rodgers had not been required to surrender himself for the execution of a judgment. Something still remained to be done before he

could be said to have been "convicted." In the absence of a final judgment of conviction, the board was without authority to revoke his license.

The Supreme Court affirmed the judgment of the court below, setting aside the revocation order—*State Medical Board v Rodgers (Ark)*, 79 S W (2d) 83

Malpractice Gauze Pack Intentionally Left in Abdomen.—The physician-defendant, the chief surgeon of a hospital owned and operated by the defendant Pittsburgh Plate Glass Company, removed the plaintiff's gallbladder and appendix, Nov 18, 1930. Three weeks after the operation the plaintiff was discharged from the hospital to her family physician. The incision did not heal, it continued to discharge pus and a "boil-like" formation developed. In February 1931, about four months after the operation, the plaintiff's condition became so serious that she returned to the hospital, where she was again under the care of the physician-defendant. At that time he alone knew that a gauze pack was in her abdomen. He treated the wound by cleansing it and applying hot applications, but he did nothing toward removing the gauze. After about ten days the plaintiff again returned to her home. On March 11 the wound opened and a gauze pack appeared at the surface. The plaintiff was immediately returned to the hospital, where the physician-defendant opened the abdomen and removed the gauze. The plaintiff thereupon sued the physician-defendant and the company operating the hospital. From a judgment of the trial court in favor of the plaintiff, for \$10,000, the defendants appealed to the Supreme Court of Missouri.

The plaintiff charged the physician-defendant with negligence in leaving the gauze pack in her abdomen and thereafter failing promptly to discover it. The physician testified, however, according to the record, that in the course of the operation there was dangerous bleeding and that "to stop the hemorrhage he fastened this gauze sponge or part of it to the liver and intentionally left it there after he sewed up the wound, except a small hole about as large as a finger left open for the purpose of drainage." He admitted that he made no record to show that he left a gauze pack in the plaintiff's abdomen and that he told no one of his having done so. He admitted, too, that it was not possible to heal a wound with a foreign body in it, and he sought to justify his failure to remove the pack by pointing out that it would have been necessary to open the wound in order to do so and that that might have caused further hemorrhage. But according to the plaintiff's testimony the physician-defendant, when he removed the sponge, remarked "Let's not let that happen again" and requested the plaintiff not to mention it, as it would harm him professionally if she did so.

If the physician-defendant's testimony is believed, said the court, that he purposely left the gauze in the wound to stop a dangerous hemorrhage and that this was necessary and proper treatment it would refute the plaintiff's charge of negligence so far as it was based only on the defendant's duty to remove all gauze before closing the incision. The physician-defendant contended that the plaintiff had complained only of his failure to remove the gauze before closing the incision. He contended, therefore, that the instruction given by the trial court to the jury was in error so far as it permitted the jury to bring in a verdict against him if it found that he was negligent if he permitted the gauze to remain in the plaintiff's abdomen for an unreasonable length of time. With this contention, however, the Supreme Court did not agree. The plaintiff charged negligence based on the defendant's failure to discover in proper time that gauze had been left in the abdomen. Moreover the physician-defendant himself, when he testified that it was proper to leave the gauze in the abdomen in this case, raised the issue as to the length of time it might be left in, while it might not be negligence to leave a gauze pack in the abdomen long enough to stop hemorrhage, it was a grave question of negligence to leave it in for five months.

The physician-defendant objected to the instruction given by the trial court authorizing a finding of negligence if the defendant did not exercise "reasonable skill and care" in failing to remove the gauze. He insisted that the degree of care required of physicians is more accurately expressed as being "such skill and care as is ordinarily possessed and exercised by members

of that profession in good standing practicing in similar localities." But no one can complain, said the Supreme Court, that a given instruction imposes on him a less degree of care than that imposed by law, and the court could not say that an instruction imposing on a physician the exercise of "reasonable skill and care" imposed a higher degree of skill and care than that used by ordinary skilful and careful surgeons in like operations under like circumstances in the same and similar localities.

The judgment of the trial court for \$10,000 against the physician-defendant and the corporation operating the hospital was, in the judgment of the Supreme Court, not unreasonable. It was therefore affirmed—*Null v Stewart (Mo)*, 78 S W (2d) 75

Chiropractic Injunction Not Available to Prevent Illegal Practice.—The Chiropractic League of California petitioned for an injunction to restrain two licensed chiropractors, practicing as partners, from employing certain modes of treatment. What the nature of that treatment was does not appear in the record, but the League contended that the use by the respondents of the modes of treatment complained of was not authorized by their licenses, that it constituted a menace to public health and that consequently it constituted a public nuisance that could be enjoined. From a judgment enjoining them, the two chiropractors appealed to the district court of appeal, first district, division 2, California.

Injunction, said the district court of appeal, is expressly forbidden by the Civil Code, section 3369, as amended by the Laws of 1933, page 2482, as a means of enforcing a penal law, except in a case of nuisance or unfair competition. The practice of the healing art in violation of a statute is not a nuisance per se. Moreover, unless the respondents in this case are not competent to practice the modes of treatment complained of or else such modes of treatment are in themselves injurious to patients, the use of such methods by the respondents would not constitute a nuisance. If such modes of treatment are not a nuisance, a statute forbidding their use would not make them so, since it would not affect the competence of the practitioner or the benefit or harm incident to treatment. The court of appeal could find no evidence to support the finding of the trial court that the use of the methods complained of was dangerous or injurious to health or show that the respondents lacked the skill necessary for the safe use of such methods and treatment and were therefore dangerous to the public. In the absence of a statute expressly authorizing the issue of injunctions in cases such as this, the injunction issued by the trial court was improper. The judgment of the trial court was reversed—*People ex rel Chiropractic League of California v Steele (Calif)* 40 P (2d) 959

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below

Susceptibility to Cancer of Inbred Mice—Kreyberg describes the segregation of 1,200 albino mice from a heterozygous material, by inbreeding of two lines of mice, which as regards tar cancer and breast cancer show opposite reaction. The line with high spontaneous breast cancer incidence shows a low tar cancer incidence and vice versa. The breast cancer line has in the females shown that they are very "cancerous". According to Lacassagne's investigations the males in this line should respond to injections of estrogenic substance with the formation of breast cancer just as readily as the females. Under natural circumstances the males do not develop breast cancer because the adequate stimulus is not produced in the male body. If the cancer tendency of this line were of a general nature, one should expect the potentially cancerous males to respond to another potent carcinogenic principle in the absence of the first. But in this case the males of line 27 have shown no such reaction. They have shown the same low tar cancer incidence as their sisters. It does not seem permissible to designate a certain strain or line of mice as "cancerous" or "cancer resistant" without at the same time designating the special type of cancer that has been investigated. It has been established by this experiment that a certain strain or line of mice may show a very high incidence of breast cancer and at the same time show a relatively low susceptibility to development of tar cancer. It is important to examine the males and the females separately. Vice versa a certain strain or line may show a very high susceptibility to the development of tar cancer and at the same time show a breast cancer incidence close to zero. The nonmanifestation of breast cancer may be caused by a hormone secretion insufficient to produce these tumors, an insufficiency which may be genetically determined as indicated by the experiments of Korteweg and Lacassagne. Tar painting has been shown to be an adequate irritant in the control material and accordingly sufficient for a fair comparison. The results

of Lynch Reinhard and Candee, Korteweg, Dobrovolskaia-Zavadskaja and Olch, and the author indicate that the susceptibilities to different forms of cancer are genetically different. The possible existence of a general cancer disposition, as outlined for man by Cramer, cannot be discussed on the data available from experimental research at the present time. A strain of mice, according to the author's present knowledge, may very well be nonsusceptible to tar cancer and breast cancer and at the same time be highly susceptible to another type of cancer but not showing this susceptibility because the specific, unknown stimulus is not present. Indications regarding a general cancer disposition may, to a certain degree, be obtained if the simultaneous application of a potent tar and a potent hormone preparation in different strains or lines gives different tumor incidences for the two stimuli separately but the total incidence is constant.

Sacrococcygeal Teratoma—Renner and Goodsitt present a case of congenital sacrococcygeal tumor in which there were two distinct tumor masses (1) a cystic mass behind the bone and beneath the skin, which was microscopically benign, (2) a highly malignant teratoma anterior to the sacrum and the coccyx found ten and one half months after birth, causing symptoms of obstruction. There was no anatomic connection between the two masses and apparently no evidence that the second mass arose from the first or from the same anlage as the first. The posterior tumor is believed to have arisen as the result of some defect in development of the spinal cord and vertebral canal, while the anterior tumor most probably arose from the neuroenteric canal or postanal intestine.

Periarthritis Nodosa Without Peripheral Nodules—Bernstein cites a case of periarthritis nodosa without peripheral nodules in which the diagnosis was suspected and verified by biopsy of a muscle before death. The abnormalities encountered were polyneuritis disturbances of vision and hearing, hypertension with evidence from examination of the urine of renal disease fever tachycardia edema anemia with leukocytosis and eosinophilia, a positive Wassermann reaction and the systemic manifestations of a chronic wasting illness. Anasarca at first thought referable to reduced total blood proteins persisted after these had been restored to a normal level. Syphilis was assumed to have no etiologic relationship to the patient's main illness.

The early course of the disease transpired during a period of persistent antisiphilitic therapy. There were wide oscillations of the blood pressure, suggesting the diagnosis of periarteritis nodosa. The rapid progression of hypertension with an initial elevation of pressure followed by a temporary decline and once again steady increase first called to mind the possibility of periarteritis nodosa explaining the symptoms. There was occlusion of a central retinal artery, while the smaller retinal vessels showed only minimal constriction in caliber. Deafness in periarteritis nodosa is uncommon. The otitic involvement was of the nerve type. The auditory nerves may have been attacked in periarteritis nodosa in the same manner as the peripheral nerves.

Bronchogenic Carcinoma.—Wasch and Epstein report fifty-four proved cases of primary bronchogenic carcinoma, with an analysis of the symptoms. Of fifty-one cases studied roentgenographically, a positive diagnosis was made in twenty-three, and in twelve the diagnosis was suggested. Pleural effusion obscured the changes in four. The diagnosis was not made in the remaining twelve cases. Bronchoscopy was done in thirty-one cases, in twenty-six of these the diagnosis was established. Three cases, in which the diagnosis was not made, were unusual in that the lesion occurred in a subdivision of the main bronchus and was, therefore, inaccessible to the bronchoscope, no biopsy was done in two. Bronchoscopy is the most valuable single diagnostic aid. However, since roentgenograms are readily obtained, a roentgen study should be the initial diagnostic procedure. Though the roentgenogram may be negative, bronchoscopy should be urged in all cases in which the clinical picture is suggestive. It is these very early lesions, not demonstrable roentgenologically, that may be most benefited by treatment. The outlook for a patient with bronchogenic carcinoma is discouraging. Until recently, the prognosis was invariably fatal. Within the past few years more encouraging reports have appeared in the literature. The important problem is to diagnose the case sufficiently early to allow surgical intervention or efficient radiotherapy. The disease is now passing into that stage of its history in which the diagnosis is no longer sealed with a forlorn hope, but rather by its early detection opens the possibility of radical or palliative therapy.

Angina Pectoris and Heart Block.—Boas states that of nineteen private patients with aortic stenosis four had classic angina pectoris, illustrating the gradual development of the anginal syndrome with the progress of the aortic narrowing. In the first case the evolution of the symptoms paralleling the advancing valvular lesion is particularly striking. In this case, the necropsy revealed essentially normal coronary arteries. On the basis of the prevalent theory that the anginal syndrome is caused by anoxemia or ischemia of the cardiac muscle, the mechanism in these cases is readily understandable. The blocking of the blood flow to the myocardium takes place at the aortic orifice instead of in the coronary arteries themselves. A casual inspection of some of these valves deformed by calcified nodules reveals how extreme this obstruction can be. Moreover, it impairs the blood supply in the territories of both right and left coronary arteries simultaneously, in contrast to the more localized area of impeded blood flow usually occurring in coronary arteriosclerosis. In the fourth case the anginal syndrome was always more accentuated when, as a result of the appearance of heart block, the heart rate dropped to 40. Because of the narrowed aortic orifice, the heart could not compensate for this slowed rate by increasing the stroke volume, so that relative ischemia of the cardiac muscle occurred. When the aortic orifice is greatly narrowed, rapidly developing heart failure by still further retarding the blood flow through the minute opening may induce an acute myocardial ischemia analogous to that following coronary artery thrombosis and giving rise to identical symptoms. This is illustrated by the sudden death of patients. Angina pectoris has often been noted in patients with aortic insufficiency, and, since all the author's patients had aortic insufficiency as well as stenosis, it might be asserted that it was the incompetence, rather than the narrowing of the valve that was responsible for the cardiac pain. The clinical manifestations of a conduction defect in patients with aortic stenosis, while not as frequent as the anginal syndrome, is not uncommon.

- Effect of Exercise on Heart in Athletes.—The Patersons state that a walking marathon race of 31 miles provided an opportunity for making various observations on the response of the heart to exercise. From planimeter measurements of roentgenograms, it was found that the size of the heart decreased after severe exercise in all the subjects observed. This diminution was seen both in the anteroposterior and in the lateral views of the heart and averaged 17.5 per cent in

the former and 125 per cent in the latter. The maximal diminution observed was 30 per cent seen in two cases in the anteroposterior view. This decrease bore no apparent relationship to the increased heart rate, and it persisted after the heart rate had returned to normal. The diminution of the size of the heart, therefore, is not comparable with that which has been shown to occur when the heart is accelerated without physical exertion. The decrease in heart size could not be correlated with the athletic ability of the individuals. No significant changes occurred in the electrocardiograms.

Tuberculous Cysts of Knee Joint—Elliott points out that the diagnosis of tuberculosis of the knee joint is frequently a difficult problem. Even with the history, clinical observations, roentgenograms, tuberculin reaction and guinea-pig tests, a preoperative diagnosis is often impossible. Tuberculosis of the knee joint may be present with entirely negative roentgen signs. On the other hand, all the usual changes characteristic of typical joint tuberculosis may occur in nontuberculous lesions. The diffuse demineralization of the adjacent bone may be present in any inflammatory lesion that involves the synovial membrane and may be as great as that seen in advanced tuberculosis. The marginal erosion described by Fraser, which represents the early invasion of bone at the synovial reflexion, has also been shown by Allison and Ghormley to occur in cases of proliferative arthritis. The subchondral infiltration described by Phemister frequently does not alter the visualized joint margin until late in the disease and even then the roentgen observations may not differ from those of a chronic osteoarthritis of other origin. Invasion and bone destruction of the epiphysis may present changes not distinguishable from syphilis or other infections of the joint. The smooth-walled cysts simulating osteitis fibrosa cystica must also be considered a definite manifestation of joint tuberculosis. The two cases presented show that such tuberculous cysts occur in the knee joint as well as in the hands and feet, as described by Jungling, and in the shoulder and elbow, as described by Van Alstyne and Gowen. However, these cysts are not pathognomonic of tuberculosis and there may be no definite roentgen changes to differentiate them from true osteitis fibrosa cystica. It should be remembered that cysts occurring in the knee joint may be tuberculous in origin, and the discovery of such cysts in a chronic gonitis should indicate an early biopsy to establish the diagnosis.

Reaction of Anterior Pituitaries of Rats to Injections of Pregnancy Urine Extracts—Wolfe gave twenty mature female rats daily injections of 25 units of pregnancy urine extract for 140 days. At necropsy it was revealed that the weight increases in the pituitaries and the ovaries which such injections induce in short time experiments, had failed to persist in most rats. The weights of these glands had decreased and in some instances had approached the normal or were below normal. The pituitaries which had declined to a normal or an almost normal weight presented a normal relative level of eosinophils which were well packed with granules. In pituitaries in which the weights were still high, these cells were reduced in relative percentage and exhibited loss of granules. There were intermediate variants between these two extremes. The weight and the morphologic changes in the anterior pituitaries were correlated with the weight and the morphologic condition of the

ovaries. Loss of granules and a reduction in their relative percentage was associated with the presence of large corpora lutea in the ovaries. The basophils of all glands were depleted of their granules and their relative percentage remained below the normal level. Injections of pregnancy urine extracts resulted in many mitoses in the chromophobes and a lesser number in the eosinophils. The result was an increase in the total number of cells in the glands. The part played by this factor in increasing the weight of the pituitary is discussed.

Obstructive Jaundice—MacGuire states that to improve the clotting time in obstructive jaundice transfusions of whole blood and dextrose solutions should be administered. A 10 per cent solution of calcium chloride and ampules of calcium agglutinate are also useful since they increase the blood calcium. Chloride deficiency is improved by the introduction of physiologic solutions of sodium chloride and diluted hydrochloric acid solutions by mouth. One drachm (4 cc.) should be given daily in divided doses gradually increasing the amount. Insulin should be administered in cases showing increased blood sugar. The diet consists of various fruit juices and cereals, unless contradicted by some special complication. These patients suffer a fall of body temperature during the operative procedures. This has to be counteracted by using hot laparotomy pads, short exposures and a warm operating room. The loss of fluids, caused by the drainage, must be counterbalanced by the introduction of dextrose and saline fluid. After the first seventy-two hours the drainage tube may be clamped for a certain time each hour in cases in which it is possible to do so. The time factor is one of the most serious considerations because, at best, the patients are poor surgical risks. It is essential to make sure that the drainage tubes, buttons for anastomosis, and syringes are in perfect condition before operating.

Radium Burns of Rectum—David points out that two gross types of reaction to radium irradiation are seen in the rectum: hyperemia and actual necrosis or ulcer formation. Hyperemia, which is practically always observed after any considerable irradiation of the rectum, usually develops in from ten days to two weeks and increases in intensity up to from three to six weeks at which time it slowly recedes. Ulceration or third degree burns may be diffuse or local in which event a persistent indolent ulcer replaces the neoplastic ulcer that was irradiated. Owing to connective tissue contraction, radiating lines of constriction are seen in the mucous membrane surrounding the ulcer, and the mucosa appears smooth and atrophic, without its usual delicate folds. In four of the author's patients the ulcer was over the prostate at the former site of the carcinoma and was firmly adherent to the prostate and immobile. Histologically, the picture was typical of ulcers following irradiation in any part of the body. For purposes of discussion he selected eight cases presenting marked radium burns. In six of them the burns resulted from treatment of carcinoma of the

rectum and in two from treatment of hypertrophy of the prostate and leukoplakia of the rectum, respectively, by the local application of radium. Of the six radium burns following treatment of carcinoma there was suggestive gross evidence of carcinoma in two. In the other four patients the lesion was a flat ulcer with marked scar tissue contraction about it and had no characteristics of a carcinomatous ulcer. When these six radium burn ulcers were examined histologically, three showed definite evidence of carcinoma in the depth of the ulcer under the necrotic exudate, and in two degenerated cells were found in the base of the ulcer, which were histologically suggestive of carcinoma. In the sixth patient, who had a destructive adenoma removed and radium needles planted into the rectum at its base, the resulting burn was not in any way typical of carcinoma and repeated biopsies over a period of five years showed no tumor cells. This patient died of pneumonia and no postmortem examination was obtained. In the five patients having radical removal of the rectum a careful dissection of the specimens for involved lymph nodes showed positive changes in one instance. Pathologically, in these six patients, three showed definite evidence of carcinoma, two probable evidence and one no evidence of tumor cells in the burned area. Clinically, only the one patient with the small burn following irradiation of the destructive adenoma was only moderately uncomfortable. The remaining seven patients were practically incapacitated. The radical removal of the rectum was made very difficult because of loss of the normal cleavage planes by reason of extensive fibrosis and dense adherence of the radium burn to the prostate in three patients, in whom it was necessary to remove the posterior one fifth to one third of the prostate by knife excision to remove the necrotic area of the burn entirely. In the patient with extensive burn following treatment of prostatic hypertrophy, the rectum was split open posteriorly after removal of the coccyx and the burn was thoroughly excised and the adjacent mucosa mobilized to cover the defect as much as possible. All the patients recovered from the operation. One has since died of carcinoma, having local as well as general recurrences. The remaining six are well and free from recurrence, from one to two and one-half years following the operation. It seems evident that, when carcinoma of the rectum is treated by radium and a burn results, carcinoma may still be present in the base of the burn or in the lymphatic nodes and radical removal of the rectum is indicated. If a radium burn in the rectum results from treatment of other lesions, local removal of the burn is the treatment of choice, as applies in radiation burns elsewhere in the body.

Vertigo as a Cardinal Symptom—McMurray points out that vertigo is not an otologic problem except when it occurs as a complication in cases of acute or chronic suppurative otitis media. The aurist can be of aid in determining the cause of the vertigo, but not more than the ophthalmologist. In many cases of intermittent vertigo of a severe type the hearing and labyrinths are normal so far as can be determined by the present methods of examination. It is possible that the lesion is located somewhere along the labyrinthine pathway on the way either to or from the cerebral cortex. Whether the exciting cause is a disturbance of water metabolism, as suggested by Kopetzky and Dederding, the sensitivity of the nucleus, vestibular nerve or labyrinth itself to sodium, as suggested by Furstenberg, Lashmet and Lathrop, or to toxins from a distant focus or protein sensitization cannot at present be determined. All patients with true vertigo should be thoroughly examined and all possible foci of infection eliminated, as there is sufficient evidence to warrant the conclusion that infection may be the etiologic

factor. In cases of Ménière's symptom complex, if the side of the offending lesion cannot be definitely determined, section of the vestibular nerve does not promise brilliant results.

Vaccination Against Tuberculosis with Calmette-Guérin Bacillus—Clawson discusses experiments concerned with immune reactions to determine the safest method of using the Calmette Guérin bacillus in developing resistance to bovine and human tuberculosis. The BCG vaccine was administered as living organisms subcutaneously and intravenously and as heat-killed organisms in the same way. The vaccine so administered was studied in respect to safety and to resistance. No mechanical injuries were observed from vaccinating many animals by each of the four methods. No toxic results, either immediate or delayed, were noted in the normal animals after vaccination. With large doses given intravenously to animals already allergic, extreme collapse and death took place within twenty-four hours, but ordinary doses were not accompanied by toxic effects in the allergic animals. Subcutaneous injections of the vaccine into allergic animals had no ill effects. In allergic animals vaccinated with relatively small doses intravenously, small, nonprogressive tubercles frequently developed in the lungs, liver and spleen. It would seem that vaccination of persons should be limited to those not having a positive reaction to the cutaneous tuberculin test. The frequency and degree of allergy were greater after vaccination by methods in which the living organisms were injected, but even by these methods allergy did not develop in all animals. A relatively small amount of allergy was produced in the animals given subcutaneous injections of heat-killed organisms. No animals vaccinated intravenously with heat-killed organisms became allergic. Severe allergy following vaccination disappeared in about three months. This disappearance of allergy was probably more rapid than in persons in whom allergy is so frequently due to arrested active lesions. But it seems probable that any allergy, especially of the smaller degrees, which develops in the course of vaccination with BCG should not be looked on as a serious handicap. Allergy in association with vaccination and probably with the development of a tubercle has been found to appear in from one to three weeks. If allergy had not appeared in three weeks after the last injection of the vaccine, it was found that it would not occur. Allergy definitely tended to disappear before resistance. The experiments seemed to show that there is no proportionate or necessary relation between allergy and the immune bodies, agglutinins, complement fixing antibodies, opsonins and lysins. In this respect, allergy in tuberculosis seems to differ from the Arthus phenomenon. A high antibody content could be developed in animals without allergy, on the other hand, a high degree of allergy could occur without measurable antibodies. Allergic animals were desensitized so that they failed to give a positive Mantoux reaction, and in the process of desensitization the number of antibodies was greatly increased. Allergy never occurred in animals in which lesions could not be found. Only living organisms injected intravenously produced small, nonprogressive tubercles in the lungs, liver and spleen. As far as safety in the process of vaccination with BCG is concerned all methods are safe except the injection of the living organisms intravenously. Evidence of resistance due to vaccination against the virulent bovine strain of the tubercle bacillus in rabbits and against the virulent human strain in guinea-pigs was shown (1) by a correlated increase in the titers of agglutinins, complement fixing antibodies, opsonins and lysins and (2) by actually preventing or greatly retarding the development of tuberculosis in rabbits and in guinea-pigs after inoculations with virulent strains of tubercle bacilli.

Streptococcus Agglutinins and Antistreptolysins in Rheumatoid Arthritis—Blair and Hallman demonstrated agglutinins for hemolytic streptococci in high titer in the serums of a majority of patients (85 per cent) with rheumatoid arthritis. Agglutination of hemolytic streptococci in high titer by a large percentage of serums was not obtained in other chronic arthritides. No correlation was found between the agglutination titer and the age of the patient duration of the disease

number of joints involved or sedimentation rate in cases of rheumatoid arthritis. Antistreptolysin was present in titers above the normal range in the serums of patients with proved infections by hemolytic streptococci and with acute rheumatic fever. There was a tendency for the antistreptolysin titer to return to within the normal range some time after convalescence. Antistreptolysin in titers definitely above normal were found in about one third of the serums from patients with rheumatoid arthritis. With one exception, these high titers accompanied high agglutination titers. The presence of agglutinins for hemolytic streptococci in serums from patients with rheumatoid arthritis is suggestive of an association of these organisms with this disease. Additional suggestive evidence may be offered by the presence of antistreptolysin, when it is found in titers above normal.

Action of Carbohydrate and Protein in Hypothyroidism Following Ablation of Thyroid—Landowne studied the specific dynamic action after the ingestion of from 70 to 95 Gm of carbohydrate in eleven instances on nine patients, at times varying from two to twenty-one months after total thyroidectomy. The average basal metabolic rate at the time of the eleven tests was minus 30.5 per cent. The oxygen consumption increased in each instance after the carbohydrate meal the increase lasting from two to four hours. The average of the maximal increases over the basal oxygen requirements was 16 cc of oxygen per minute, or 101 per cent, and the average total increase was 1,400 cc per minute, or 44 per cent, for the average duration of the experiments (three and a third hours). These results are interpreted as demonstrating the presence of specific dynamic action of hexose in human hypothyroidism following total ablation of the normal thyroid. Although this specific dynamic action appears in percentage to be approximately equal to, it is, on an absolute basis, somewhat less than the average of figures for normals taken from the literature. The specific dynamic action after the ingestion of from 54 to 102 Gm of protein was studied in five instances on four patients, at times varying from four to twelve months after total thyroidectomy. The average basal metabolic rate at the time of the five tests was minus 28.6 per cent. The oxygen consumption increased in each instance after the protein meal the increase lasting at least from six to seven hours. The average maximal increase was 29 cc per minute (20 per cent of the basal oxygen requirement) and the total increase over the observed period (from six to seven hours) was 10,570 cc (16.6 per cent of the basal oxygen requirement), or 14,000 cc per hundred grams of protein. These results are interpreted as indicating the presence of a specific dynamic action of protein in the totally thyroidectomized hypothyroid human subject. The extent of the specific dynamic action is within the range of normal as compared with values found in the literature.

Ureteropyeloneostomy for Hydronephrosis—In performing Lubash's ureteropyeloneostomy, the ureter is removed from its original site as near its insertion to the pelvis as possible, as the strictured area is utilized in its reimplantation. From this point on, the ureteropyeloneostomy of Kuster is carried out. The difference lies in the method of anastomosis. The ureter is incised downward on its anterior and posterior surface for a distance of 2 or 2.5 cm. and, after its insertion into its new mouth at the most dependent portion of the renal pelvis, the straps of the ureter are drawn outward laterally from the pelvis through two very small stab wounds on either side of the new neostomy opening and a mattress suture is employed to fix them in position. The knots are placed outside the renal pelvis. From this point on, Papin's method of trans-renal drainage and resection of the redundant pelvis is carried out. Both the Garceau catheter that splints the new anastomosis and the Pezzer catheter that drains the kidney are brought out through the same nephrostomy wound. Nephropexy is employed if the kidney is mobilized. The author believes that the new features that he has added will help overcome some of the former handicaps of the operation, by reason of the following deductions: (1) there is little or no tension at the new point of anastomosis, (2) the true diameter of the ureteral orifice remains intact, as no sutures through its edges serve to cause shrinkage from scar tissue formation, (3) the two strap-like projections are brought outside the newly established pelvis, preventing any possibility of obstructing valvelike formation and (4) at the same time reducing tension from the point of anastomosis, and (5) no puckering or buckling can occur.

Acute Suppurative Disease of Petrous Pyramid—Quittner and Gross believe that the problem of the treatment of otitic meningitis and other intracranial complications lies mainly in their prevention. This implies the early recognition of impending intracranial disease and the institution of measures to prevent further advance of the process. The line of attack must follow the path of infection into the intracranial cavity and this can usually be suspected from the history of the development of the symptoms and a knowledge of the existing pathologic changes. In the case reported the persistence of an elevation of temperature and the leukocytosis following a mastoidectomy indicated the continuance of an infective process. The deep facial pain pointed to the petrous pyramid as the most probable location of the lesion. Deep seated homolateral facial pain, often referred to the temporal region and forward around the eye, is often the first symptom of an infection of the petrous pyramid and may exist without external rectus palsy. This early evidence of localized meningeal reaction may be manifested by an increase of cells in the spinal fluid and an increase in the spinal fluid pressure. The removal of the extradural septic focus and the institution of proper drainage at this time may prevent the development of a frank bacterial meningitis. Clinical signs of meningitis may be lacking even when many cells and organisms are found in the cerebrospinal fluid. This condition prevailed in the case reported, since at the time of the first puncture 8,000 cells and many organisms were found, yet none of the usual clinical signs of meningitis were present. It is highly probable that, had a spinal puncture been done earlier in the preoperative course, the fluid would have yielded an increase in cells without organisms. The optimal time for operative intervention is when meningeal irritation exists without an actual bacterial meningitis. The approach to the petrous pyramid described by the authors proved to afford a satisfactory exposure and adequate drainage. The lesson to be learned from the case reported is the importance of doing a lumbar puncture early when an intracranial complication is suspected following middle ear disease. When a needle of small caliber is used and only enough fluid is removed for the required examinations, the procedure is practically without danger. To delay a lumbar puncture until signs of a frank meningitis develop is to lose valuable time during which an overwhelming invasion of the meninges may occur.

Heart Disease in Children.—Gilkey believes that it may be possible through familial incidence to ascertain what children are most susceptible to cardiac disease and to institute a few preventive measures at an early age and thus possibly obtain better results. The common cold is of great importance (especially during the winter months) and may be the cause of a reactivation with a fatal outcome. Possible danger of colds, sore throats and other infections should be explained and reiterated to the patient. Although there is no positive proof that the routine removal of tonsils prevents primary manifestations or minimizes reactivations of rheumatic fever, the author believes that a clear throat will predispose less to infection of the upper respiratory tract. A careful study of the sinuses is still justified in the type of child included in this study. Tonsillectomy is an important factor in preventing endocarditis. The mortality rate is nearly 50 per cent less in children whose tonsils had been removed before the initial attack. The valve or number of valves involved in rheumatic heart disease has little to do with prognosis as compared to the virulence of the infection, the resistance of the host and the number of reactivations. The average time of manifestation is ten years. Familial incidence is as great as in tuberculosis. The use of intravenous preparations of hemolytic streptococci with the hope of lessening hypersensitivity is still in the experimental stage but offers some hope. Complement fixation may be used as a measure of the antibody content of serum of the patient but is not as reliable as the skin tests to indicate sensitivity.

Trichomonas Vaginalis, Monilia Albicans and Leukorrhea.—Karnaky speaks of two common causes of a discharge and a vaginitis. *Trichomonas vaginalis*, a protozoan, and *Monilia albicans*, a fungus. They are often overlooked because a fresh smear is seldom examined in patients complaining of a discharge. Also, few technicians are told to look for these organisms and few are able to recognize them. *Trichomonas vaginalis* is capable of causing a malodorous discharge. Usually in *Monilia* infections spots are seen in the vagina of gynecologic and flakes in that of obstetric patients. In the differential diagnosis of *Trichomonas vaginalis* the discharge increases after the menses and persists despite most methods of treatment, there is constant leukorrhea in most cases, itching around the vulva is common the discharge scalds or burns the thighs whenever it comes in contact with them and local application of gentian violet alone will not clear the infection, the parasite is seen in pregnancy as well as in nonpregnancy, is diagnosed by examining a fresh smear, is not so often seen in stained smears produces a malodorous discharge, is a protozoan and causes itching right after menses and more often during the day. In *Monilia albicans* the discharge increases before the menses and is easily treated, there is a remission in the production of the discharge, itching around the vulva is not so common the discharge apparently does not burn or scald the thighs, gentian violet clears the infection almost instantaneously the parasite is seen most commonly during pregnancy and is not so common in gynecologic patients, is diagnosed by a fresh smear, is seen best in stained smears, apparently does not produce a malodorous discharge is a fungus and causes itching at most any time and more so at night. The dry method of treatment with corn starch is given. It is concluded that a 2 per cent solution of ethyl alcohol gentian violet or a 5 to 7 per cent aqueous solution of gentian violet is better for the treatment of *Monilia albicans*. The male is apparently a source of infection and reinfection. *Trichomonas vaginalis* is a common cause of postoperative leukorrhea. *Trichomonas vaginalis* is recognized as a pathogenic organism.

Hyperpyrexia in Treatment of Bronchial Asthma.—Phillips and Shikany studied the value of hyperpyrexia in fifty cases of bronchial asthma. Practically all other therapeutic factors were eliminated. Clinical biochemical and laboratory

studies were carried out on all patients in order to determine the physiologic and biochemical changes associated with the treatment. Attention has been called to the clinical and laboratory data which indicate a lowered general metabolism in asthma. Improvement followed fever treatments and the clinical results indicate that 82 per cent received definite benefit. Biochemical and laboratory studies, however, indicate that more than 40 per cent of these were possibly only temporarily relieved. At present, after an observation period of six months, 32 per cent seem to have obtained lasting relief. The author believes that ten treatments should be the minimum of a course. It would appear that from twelve to fifteen are possibly still better, but apparently there is no improvement beyond this number. Two treatments a week are preferable. Temperatures maintained above 105 F rectally have no advantage over those ranging from 102 to 105 F. Temperatures sustained for four hours produce results comparable to those extending over longer periods.

Early Diagnosis of Chorionepithelioma—Mathieu and Palmer report the early diagnosis in a case of chorionepithelioma, in which following the curettage for the removal of hydatid material the patient was absolutely free from symptoms. There was no more bleeding, her blood count increased, the uterus and pelvic contents were normal to palpation, she was in good health and free from complaints and she had gained weight. There was no cough or any sign of lung involvement. The sedimentation rate remained slightly increased and the Friedman test was persistently positive. The authors have been able to follow the continuity of the progress through pregnancy and hydatid mole, chorionepithelioma and eventual cure. The free use of the Friedman test revealed the sequence of events before and after operation. The diagnosis rested entirely on two facts: the history of mole and the persistence of anterior pituitary-like substance in the urine. Whether or not there can be a negative pregnancy test in the presence of chorionepithelioma can be determined only by critical observation of the results obtained in testing for the pituitary substance in many cases of known chorionepithelioma. It may eventually be possible to foretell the degree of the malignant state of a known chorionepithelioma by biologic quantitative assay of the patient's urine. It seems reasonable to believe that in cases of chorionepithelioma, diagnosed early, one need not remove the ovaries. In the authors' case only a supravaginal hysterectomy was done and there was no evidence of extension, recurrence or metastases after two years. In another case, a complete hysterectomy was done because of severe lacerations of the cervix, and the right ovary was removed only because it was firmly adhering to the posterior sheaf of the right broad ligament. The patients were both young women,

and it hardly seemed reasonable to remove ovaries that had all the gross appearance of being normal. The results seem to have justified the procedure. The authors believe that chorionepithelioma may be definitely diagnosed shortly after its inception. Every patient who passes a mole should have her urine examined for anterior pituitary-like substance by the Friedman test monthly for at least a year. In this way a developing chorionepithelioma might be diagnosed early and removed before symptoms appear or before metastases develop.

Internal Frontal Hyperostosis—Moore points out that internal frontal hyperostosis is by no means the medical curiosity that the percentages he gives appear to make it. There is a total of sixty-five cases described in the literature, all but three being either necropsy reports or composed of museum specimens. To this number seventy-two living examples of the condition have been added. In spite of the different degrees or types of the disorder, the cases have an astonishing similarity to one another and there is variation only in the intensity of the symptoms. Against the severity of the syndrome stands the fact that there are many rational therapeutic measures that may alleviate or possibly arrest the disorder. The picture of the syndrome in its complete form has been published by several writers. Description of its less advanced development is something new. Two hypotheses regarding internal frontal hyperostosis have been offered: that there is a special mechanism for the control of calcium metabolism, existing only in the female, and that the disorder of such a mechanism is the cause of the syndrome accompanying internal frontal hyperostosis. There is presented a fruitful field for investigation of the fundamentals that underlie the physiology and chemistry of calcium and fat metabolism, and possibly a heretofore unknown structure with an internal secretion. The disease will be found with greater frequency if it is sought for. It is possible that investigation of this disorder may throw much light on neuropsychiatric pathology. There is a question as to whether or not the unknown causative factor that produces the syndrome does not also give rise to the neuropsychiatric symptoms as well as the hyperostosis. Internal frontal hyperostosis as a name for this syndrome suffers from the drawback inherent in using a single feature of a disorder to designate the whole. It is possible that the hyperostosis, though the surest sign, is the least important manifestation of the disease.

Traumatic Ossifying Periostitis of the New Born—Snedecor and his associates describe a new type of birth injury in a series of breech extractions. They conclude that the injury is probably due to (1) too strong traction on the extremity, (2) a twisting pull on the leg due to inability on the part of the obstetrician to rotate the line of traction with the rotation of the fetus as it accommodates its large diameters to those of the birth canal, (3) the inability to bring both feet down so that traction may be equally distributed and (4) the too hasty attempt to complete the delivery. In these injuries immediate roentgen examination is negative. The calcium deposit becomes visible only after one or two weeks. Recovery took place spontaneously in all the cases observed by the authors. Recovery time seems to be in direct proportion to the extent of the injury—from four to twelve weeks—and no permanent disability has resulted. In two cases the infants were followed until they walked. A tearing or stripping of the periosteum of the femur or humerus occurs most often at its weakest point of attachment, the epiphysis, and the maximal strain of the traction is imposed on the proximal epiphysis. If the trauma is more severe, the authors observed that the stripping follows down the shaft with further subperiosteal hemorrhage, as in one of their cases. Osteomyelitis and epiphysitis were both suggested in their first case. Fracture was the opinion of one roentgenologist. Sarcoma was also considered. In truth, the lesion is similar to myositis ossificans, which has its etiology in some instances, at least, in torn periosteum. A rapid proliferation of the periosteal osteophytes takes place with deposition of calcium. The roentgenologically visible periosteal injury is but part of the hemorrhage from muscle and fascial tearing. Heretofore, the cause of pain, limitation of motion, swelling and dislocation of the injured part, which are the chief clinical observations have been attributed to injury of soft tissues only.

Persistent Headache During Lactation—Beilby presents five cases of persistent headache associated with the nursing period which characteristically disappears on weaning. Of varying severity, it is usually frontal, being described as "behind the eyes", but it may affect the whole head, with spasms referred particularly to the occipital region, commencing typically at or after the first week of the puerperium. None of the patients were primiparas. No pathologic basis was traceable for this symptom. Pregnancy and parturition were normal, the urine was normal before and after confinement, except in one case in which there was a trace of albumin during the later months (summer). There was no rise in blood pressure during the puerperium; the fundi were normal. There was no uncorrected visual defect. Except in one case there was no anemia. Drugs at best gave only temporary relief. The persistent headache appears to occur chiefly among those of poorer circumstances and/or poorer physical condition, in whom nursing is an added burden. Dental caries is more likely part of the same condition than a causative factor. Treatment is prophylactic—that is, antepartum therapy with suitable diet, vitamins, iron and calcium, or, when this has been neglected or through circumstances impracticable, similar treatment applied with a view to improving the general condition during the puerperium or, finally, weaning if the symptoms justify it.

Weil's Disease and Certain Occupations—Alston and Brown state that nine of forty-five sewer workers, who were not aware of having had any form of jaundice, showed significant serum agglutinins for *Leptospira icterohaemorrhagiae*. Evidence is given that protective antibodies are present in specimens of human serum that show agglutinins. Prophylactic inoculation of those exposed to risk appears to offer a means of prevention of this disease, and work on the preparation of a suitable vaccine in a medium containing no foreign protein is in progress.

Observations on Erythema Nodosum W D MacKinnon—p 339

Erythema Nodosum—MacKinnon states that his records show that erythema nodosum had its greatest incidence about the time of an influenza epidemic, cases occurred before, during

and after the epidemic, but mostly before. Erythema nodosum occurred when an epidemic of whooping cough coincided with an epidemic of influenza. But in an extensive epidemic of whooping cough, when no influenza was present, there were no cases of erythema nodosum. Mumps occurred when influenza was prevalent and there were cases of erythema nodosum. In a large epidemic of mumps, however, no influenza was present and no cases of erythema nodosum showed up. Thus measles, whooping cough and mumps do not seem to be associated with erythema nodosum as is influenza and yet the author points out that in his experience epidemics of measles and whooping cough are more productive of tuberculosis than epidemics of influenza. Nine chickenpox epidemics were invariably accompanied by cases of herpes zoster, but only three, which occurred in association with influenza, showed any cases of erythema nodosum. Yet erythema nodosum seems to be closely connected with chickenpox and with herpes zoster. He concludes that erythema nodosum was not associated with acute manifestations of rheumatism, although the majority of the patients were of a rheumatic diathesis. The maximal incidence of erythema nodosum was in years in which the apex of incidence also occurred in other diseases, which are known to be due to the "filtrable viruses."

Treatment of Cervical and Broad Ligament Fibroids

—Cannon describes several cases and gives the following principles for the treatment of cervical and broad ligament fibroids: 1 In the case of large cervical fibroids growing from the posterior cervical wall or of large broad ligament tumors that have become retroperitoneal, the uterus should be removed with the tumor. 2 In order to minimize the amount of bleeding from the uterine vessels during the process of enucleation of the tumor the aim should be to remove the uterus by a right-to-left or left-to-right procedure before attempting enucleation of the tumor. 3 In the case of cervical tumors that are not too large and are growing from the anterior cervical wall or of broad ligament tumors that have not yet established retroperitoneal relationships, the uterus may be left, provided there is not much blood loss during the process of enucleation and that hemostasis of the myomatous bed can be secured. 4 During the removal of either a cervical or a broad ligament tumor, injury to the ureters can be avoided by working inside the capsule of the tumor. 5 Should a patient with a large fibroid complain of pain and abdominal tenderness whether the temperature is raised or not, infection of the tumor should be

considered and preliminary vaccine treatment followed by a preoperative injection of nuclei to stimulate leukocytosis should be instituted 6 If the intestine is markedly adherent to the tumor that is suspected of being infected and it is believed that the adherent intestine is the cause of the infection, instead of being separated from the tumor it should be resected if possible. 7 Should spreading peritonitis supervene in spite of all precautions, as patients die not so much from peritoneal toxemia as from intestinal toxemia, treatment based on the best current thought in regard to the pathologic changes of the condition should be instituted 8 Unless mechanical obstruction is evident, operative intervention should be postponed as long as possible.

Observations on Motor Phenomena of Hysteria—Allen investigated fifty-nine patients, who were subjected to hysteria, with particular reference to the disturbances of motor function. The essential and primary effect in the motor system is inhibition of the motor impulse to the muscle or group of muscles which in the normal subject would contract in response to that impulse. Inhibition of the motor impulse arises at the unconscious level of higher cortical functions and is produced by either a conflict in the personality, both sides of which are excluded from consciousness, or by that factor in a conflict which is excluded from consciousness to allow the other factor to control the conscious life of the personality. The immediate motor effect is inhibition of agonists and is followed by contraction of antagonists or of fixation muscles. According to the degree of inhibition, the clinical effects, in order of lessening severity, are flaccidity of muscles in the part concerned, flaccidity of muscles with contraction of fixation muscles and failure of agonists to contract followed by contraction of antagonists. The last is the most common motor phenomenon. These effects are produced in the same way whether the original motor impulse arises as a result of voluntary effort, voluntary effort at command or in response to a sensory stimulus as in eliciting the plantar reflex. The stretch reflex acts normally in the muscles of the hysterical limb, although, when the muscle is flaccid, tone is usually below the threshold at which the reflex comes into action and repeated or prolonged stretch is needed to bring it above that threshold. Local motor phenomena arise as a result of inhibition of agonists, contraction of antagonists, the application of stretch to agonists and contraction of agonists in that order. Hysterical tonic paralysis, tonic paralysis with contracture, tonic paralysis with tremor, tremor with minimal tonic paralysis and tremor are described as they occur in the hysterical subject, and their development is shown to

depend on the sequence of effects of local motor phenomena. Attention is drawn particularly to the clinical effects of these phenomena in the face, abdominal muscles and lower limb. The effect of hysterical motor phenomena on tendon reflexes and the plantar reflex is described. The need for attention to every detail in the examination and interpretation of the plantar reflex is stressed.

Abnormalities Presented by Brains of Mental Defectives—From a study of thirty-one defective brains Berry observed that the defective brain is 20 per cent smaller than that of the lowest normal, that even within this low standard the range of variation is considerable and that there is a measurable disproportion between the main prerolandic and postrolandic cortical constituents, this disproportion being particularly noticeable in the parietal region. In view of the anatomic position of the parietal lobe relative to the cuneus, superior temporal lobe and postcentral gyrus—that is, to the cortical areas at which visual, acoustic and somesthetic impulses are received first—it seems impossible to doubt that, when the parietal lobe is underdeveloped, as in these defectives, the reception, association and coordination of impressions derived from the organs of special sense must be so impaired as to result in serious mental deficiency. There is, therefore, an adequate neurologic explanation of the mental status of the present series of cases. Bolton's insistence on the importance of an adequately developed and well proportioned prerolandic effector area (frontal lobe) in all normal mental activities fully bears out the present investigation and particularly the irregularities between the frontal effector area and the rest of the brain. In persons with brains so irregularly developed and so lacking in the proper proportions of receptor and effector cortices—that is, in defectives—there must necessarily be a diminished sensibility to and perception of the external world around them. They thus have to rely far too much on purely bodily stimuli from within, with results that profoundly alter their mentality and may even make them react to their human environment in an abnormal or asocial manner, and this defectives—especially the lower grade ones—most certainly do.

Serum and Vaccine in Whooping Cough.—Paterson and his associates made an attempt to produce a satisfactory test that could be used in the consulting room to show (1) whether a child has had an infection of the Bordet-Gengou bacilli on some previous occasion and (2) whether specific treatment in a noninfected child had been of any avail after a course of injections. The vaccine is injected intradermally into the flexor surface of the forearm, the result being read after twenty four and forty-eight hours. A positive test is seen as an area of hyperemia round the site of the injection, ranging in size from a sixpence to a shilling in diameter. It is transitory in nature,

and some experience is required to make accurate readings. It should be seen in twenty-four and forty-eight hours and tends to disappear after this. Just as a marked reaction may be expected in adults with the Mantoux test, the same marked reaction may be expected in adults with this pertussis test, and smaller quantities, even 0.05 cc., will give a definite positive. The authors' procedure of active immunization varies slightly from that recommended by Sauer in that three biweekly injections are made instead of three weekly ones. Alternate arms are used each time, the deltoid region being injected the first week and the triceps region the second week, the deltoid region again being used the third week. Skin tests are performed before, during and after the injection. The skin tests become positive approximately one week after the last injection. This appears to show that, contrary to what Sauer claims for the vaccine, an allergic state is developed which gives a hypersensitiveness to the skin in from three to four weeks after the initial dose of vaccine, and the child then shows a positive skin test. This gives the physician some idea as to whether or not the treatment is effective and agrees with the result of vaccination in other diseases. Whether or not immunization is complete then it is difficult to say. Possibly it reaches its height at four months, as Sauer suggests.

Pregnancy Test in Fetal Death—Bishop states that, when intra uterine death is suspected clinically, a negative pregnancy reaction will confirm this suspicion, but a positive reaction may still occur as long as three months after the death of the ovum and cannot therefore be accepted as showing that the fetus is still alive. A comparison between the estrogenic reaction and the Aschheim-Zondek and Friedman tests shows that the former becomes negative considerably sooner after fetal death than the latter. It may, however, still be positive three weeks after the death of the ovum, so that a positive result is by no means certain evidence of a living embryo. The results obtained in the cases investigated throw no fresh light on the factors that regulate the secretion of gonadotropic hormones by the placenta.

Thrombosis of Pampiniform Plexus—McGavin cites two cases of thrombosis of the pampiniform plexus because its apparently spontaneous occurrence is not familiar and the sufferers are liable to be treated by orchidectomy. Both patients were of middle age, and in both the left side was affected. In neither was there an obvious exciting cause, such as trauma or infection, nor had there been any history of preceding varicocele or an abnormal position of the testicle. In neither case were the seminal vesicles diseased, nor were there firm nodules or softened areas in the prostate. Active spermatogenesis was proceeding in one case, and there was no reason to believe that it had been stopped in the other. Microscopically the walls of the vessels in both spermatic cords gave evidence of degeneration. In one patient the pain was of sudden onset, whereas that of the other began more gradually. The pain of the one was brought on by standing, while that of the other was increased by coughing or lifting. If the patient is examined soon after the onset, epididymo-orchitis is most likely to be simulated, whether of the gonococcal, the coliform or the uncommon acute tuberculous type. Torsion of the spermatic cord may be suggested, although in the thrombosis there would not be the associated shock, and the testis would be well in the scrotum and not acutely tender. A diffuse hematocele of the cord would give a history of sudden onset of severe pain during some effort. Cases that are seen a few weeks after the onset are liable to be diagnosed as tuberculous epididymo-orchitis. In these the mode of onset, the short history, the absence of any beading of the vas and the negative rectal examination would be valuable points. The probable freedom of the tail of the epididymis from involvement may also be useful, but a hematogenous tuberculous epididymitis starting in the head is a possibility that impairs the value of this criterion. These later cases may occasionally resemble malignant disease of the epididymis. The importance of recognizing a thrombosis of the pampiniform plexus lies in its bearing on treatment. Should it be confused with certain other diseases there is a possibility of an unnecessary orchidectomy. This is especially to be avoided, since the microscopic appearances suggest that active function continues in the testicle on the affected side.

Detection of Tuberculous Bacillemia by Loewenstein Method—Calmette and Saenz assert that the culture medium of Loewenstein is superior to all the mediums so far proposed for the culture of tuberculous bacilli of human, bovine or avian origin. Of 936 blood samples, seeded on to this medium in about 6,000 tubes, subject to careful observance of Loewenstein's directions, there were only twelve positive results. The blood samples were obtained from ninety patients presenting acute or chronic tuberculosis, fourteen rheumatism and thirty dementia praecox. If consideration is limited to the blood cultures with samples from tuberculous patients, the positive results total 1.58 per cent. The appearance of the cultures showed every case to be one of invasion of the blood by small numbers of microbes only. In most cases, the isolated strain was of a human type. Cultures with thirty-seven blood samples from patients suffering from acute or chronic rheumatism and eighty-three blood samples and sixty cerebrospinal fluid samples from patients suffering from dementia praecox remained negative. The considerable difference between the percentage of the authors' positive results with 166 tuberculous patients and that of Loewenstein, and their complete failure with patients suffering from rheumatism and dementia praecox cannot be attributed to errors of technique, to differences in the sensitiveness of the culture mediums or to insufficient cooperation between clinics and laboratory. They never obtained the luxuriant appearance of the cultures of Loewenstein's own laboratory or the positive results noted on direct examination of the centrifugation deposit in cases of dementia praecox, erythema induratum and polyarthritis. The method of Loewenstein is less sensitive as a means of detecting tuberculous bacillemia than inoculation into the guinea-pig. The latter method, when used in connection with patients suffering from progressive forms of tuberculosis, yielded a higher percentage of positive results than blood cultures. The authors believe that the processes through which the blood passes in Loewenstein's method and the laking, successive washings and repeated centrifugation to which it is subjected, are injurious to the preservation of the vitality of the bacilli. They conclude that Loewenstein's theories concerning the alleged inhibitory effect of hemoglobin on the cultures are not justified and that the seeding on Loewenstein's egg medium of pure blood yields more frequent and more reliable positive results.

- Properties of Staphylococci in Diphtheria Bacillus Carriers R Dulis couet and B Ballet—p 1297
 *Lymphatic Colon Bacillus Depot in Enterorenal Syndrome H Cam bessédès and J Bourgeois—p 1300

Lymphatic Colon Bacillus Depot—Cambessedès and Bourgeois state that there are three steps in the establishment of certain urinary infections the intestinal, the intermediary and the renovesical. Less is known about the intermediary than about the others, but it is believed that the mesenteric lymph nodes are largely involved. They investigated this factor by direct injections of colon bacilli into the mesenteric ganglion followed by search for the germs in the urine and in the blood. The optimal quantity to be injected was found to be 0.1 cc. of a twenty-four hour culture diluted 1:10. Urine was obtained from the rabbits thus inoculated by sterile bladder puncture or by catheterization. Nineteen animals were used in these investigations. Ten showed a variable delay of from two to seven days before verifiable colon bacilluria set in. Three died rapidly of peritonitis from technical errors. Three showed local septic complications. And, finally, three showed no pathologic sequels whatever. Similar investigations on cats gave comparable results. In the second part of their studies the authors tried to find bacteria in the blood and to determine the moment of appearance and duration of the bacteremia. The rabbit and the cat were again used. The passage into the blood stream was apparently rapid—one hour after intraganglionic injection the blood culture was positive. The cultures become negative after twenty-four hours. Finally the agglutinative properties of the serum were studied. These were found to be unreliable and of no diagnostic value. The authors believe that the combination of these studies is indicative of an intermediary stage.

 Hemostatic Action of Human Milk. L Lindenfeld—p 1332

Arteriovenous Aneurysms—Kisthinos states that the rapidity of appearance of cardiac disorders is in direct proportion to the size and caliber of communicating vessels. The first and dominant symptom is tachycardia. The mechanism was investigated by experimental observations on dogs by producing anastomoses between arteries and veins of different sizes and locations. In all instances the tachycardia produced was considerable and occurred promptly except for the mesenteric vessels, in which tachycardia was of slower evolution. The conception that tachycardia is due to increased venous pressure was tested on dogs. This pressure was found invariably raised in the presence of arteriovenous aneurysms. Abolishing the communication resulted in prompt fall of venous pressure and subsidence of tachycardia. Another interesting symptom is lowering of the diastolic pressure. It is believed that this change is responsible for the subsequent hypertrophy and dilatation of the heart and its eventual failure.

 Significance of Crepitan Rales in Pulmonary Tuberculosis A Jousset—p 1363
 Maximal Urea Concentration and Uremia by Oliguria P Buzeu—p 1363

Hyperparathyroidism and Scleroderma—Leriche and Jung believe that scleroderma is the skin manifestation of lesions that produce an abnormal calcium content of the skin following a skeletal osteolysis due to hyperparathyroidism. The parathyroid is the initiating factor, the osteolysis the intermediary one and cutaneous atrophy the result. Patches of involved skin were studied for calcium content by biopsy and were found to contain from 20 to 30 per cent more calcium than normal skin from other regions. Furthermore, the calcium content of the fat in regions adjacent to a sclerodermic plate was almost double that found in fat from normal regions. Roentgenograms of the bone show a diffuse decalcification. The conclusion is obvious that scleroderma is a cutaneous form of chronic hyperparathyroidism and that it is as such a disease of the skeleton as of the skin.

 *Frequency and Significance of Erythrocytosis in Gastroduodenal Ulcers. L Ugelli—p 544
 Ganglionectomy in Thrombo-Angitis Obliterans and Brown Test Results P Valdoni—p 559

Significance of Erythrocytosis in Gastroduodenal Ulcers—Ugelli examined the blood of ninety-two patients suffering from gastroduodenal ulcers, the presence of which was confirmed at the operation in all cases. The presence of erythrocytosis was proved in 74 per cent of the patients suffering from duodenal ulcers, in 40 per cent having gastric ulcers and in 40 per cent of a group of persons that had had gastric resections performed from seven months to three years before the hematologic examination. In two patients presenting gastric disturbances associated with hyperchlorhydria there was no erythrocytosis. The author states that the presence of erythrocytosis is of value in the diagnosis of gastroduodenal ulcers. He discusses several hypotheses on the genesis of erythrocytosis and states that it does not originate in gastric hypersecretion. Both erythrocytosis and gastric hypersecretion are manifestations of the hypervagotonic constitution that is characteristic of ulcerous patients.

 *Hypochloremia and Hyperemesis in Pregnant Women A de Tena y Molera—p 297
 Hemolytic Photo-Erethism (Increase of Hemolysis of Blood Serum by Influence of Light) A de la Granda and F Vegas—p 302

Hypochloremia and Hyperemesis in Women After Operation—In the treatment of nonacidotic vomiting in pregnant women and in nonpregnant women after operation, de Tena y Molera resorted to rechloridation of the patients by means of intravenous injections of hypertonic salt solution in daily doses of from 5 to 15 cc. The treatment lasted for two or three days after complete disappearance of vomiting. The author concludes that the treatment is of value, for he obtained satisfactory results in 88.8 per cent of his eleven cases. In all cases in which it gives good results, marked hypochloremia exists. The fact that hypochloremia disappears when vomiting stops seems to point out that the condition is the cause of vomiting. The mechanism of the production of vomiting is explained by a disturbance of the equilibrium of the colloids in the blood serum, which, after having been altered in their structure, act either as toxic or as foreign substances by stimulating the vomiting centers in the brain or the nerve ends of the stomach. Hypochloremia in pregnant women is due to hyperchloruria that originates in disturbance of the osmoregulating functions of the kidney by action of the hormones or of gravidotoxic substances. In nonpregnant women after operations, it is due to the absorption of chlorides by the tissues especially by traumatized tissues. Hyperazotemia is not necessarily associated with chloropenia, generally the content of urea in the blood is below normal.

 Present Status of Cultivation of Bacillus of Leprosy W Kikuth and D H Verfurth—p 1435
 Dilatation of Stomach L Roemheld—p 1438

Sterility as Result of Functional Disturbance—Mayer points out that many sterile women are entirely free from local disorders. Moreover, diseases of the blood and the metabolism and endocrine disturbances producing sterility are not increasing, and yet the incidence of sterility is greater. The author thinks that in view of these facts a further searching for anatomic causes of sterility will be of no avail and that functional factors should be given attention in connection with the problem of female sterility. He points out that late marriages may be responsible for an increase in sterility, particularly in women with hypoplasia of the genital apparatus. In this connection

it is pointed out that the regular marital sex intercourse frequently causes an after-maturation of the hypoplastic uterus but the possibility of such an after-maturation is of course much less probable if the women are older at the time of marriage than if they are comparatively young. The author concedes that frigidity does not necessarily cause sterility, but thinks that it is an important factor in some cases. Psychic factors likewise play an important part in conception. The author calls attention to the possibility of sperma intoxication as the result of too frequent intercourse, to the possibility of a premature rupture of the follicle, to the period of physiologic sterility and to the fact that sterility frequently follows the prolonged use of contraceptives. He concludes that hitherto the problem of sterility has been given a too mechanistic interpretation. He thinks that in most instances it is a complicated functional disturbance, in which somatic as well as psychic factors play a part.

- *Acute Visceral Disturbances After Operations for Brain Tumors B Schlesinger—p 75
- *Diagnostic Value of So Called Extracreatinuria F Robert—p 94

Etiology of Infectious Polyneuritis—According to Deusch, polyneuritis is usually caused by toxic or infectious processes, but if such causes cannot be found, the disorder is sometimes diagnosed as idiopathic polyneuritis. The author considers this diagnosis inadvisable pointing out that careful search will usually disclose an infectious cause. He describes the clinical history of a man aged 26, in whom a typical polyneuritis with motor and sensory tetraparesis and ataxia of the type of peripheral pseudotabes developed following a phimosi operation that resulted in suppuration of the surgical wound and was accompanied by the development of furuncles on the thighs. The patient recovered following treatment with a bacterial autolysate, massage, faradization and baths. The motor and sensory disturbances subsided at first slowly and later quite rapidly. The author considers especially noteworthy the fact that the polyneuritis involved all four extremities that the symptoms were quite severe and that the oculomotor and the trigeminal nerves were involved. The fact that the patient recovered in a comparatively short time indicates that even rather severe polyneuritides of infectious origin may have a comparatively favorable prognosis.

Isolated Spastic Spinal Syndrome of Lead Poisoning—Straube and Kalbitzer point out that, in view of the affinity of lead for the nervous substance the possibility of an isolated spastic spinal syndrome cannot be denied. In this event the influence of the lead would be restricted to the central neuron of the chief motor tracts and there would result only a degeneration of the pyramidal tracts without involvement of the second motor neuron or of the sensory tracts. The authors assert that such cases are rare but they cite one case in which they had to decide whether this condition is possible. They reach the conclusion that in rare cases lead poisoning may result in an isolated spastic spinal paralysis.

Visceral Disturbances After Operations for Brain Tumors—Schlesinger calls attention to the fact that after intracranial interventions particularly those near the brain stem functional disturbances occasionally develop in the region of the sympathetic vagus nucleus or of its superordinated diencephalic centers which in turn may lead to dangerous even fatal, visceral disturbances (Cushing-Hess). In the lungs these disturbances become manifest as an abnormal permeability of the vascular walls with resulting pulmonary edema and in the region of the esophagus, stomach or duodenum as loss of substance, which may appear in all the transitional stages from hemorrhagic erosions to penetrating ulcers with their sequels. In one of the two cases described by the author (meningioma of the posterior cranial fossa) the severe pulmonary edema that developed in complete cardiac sufficiency and had a tendency

to relapse could be effectively counteracted by a puncture of the ventricle. The second patient whose history is reported died of a gastric hemorrhage. In this instance the tumor, a basofrontal meningioma, had no relations to the brain stem, however a chronic increase in the cerebral pressure had apparently produced a functional disturbance in the nerve centers mentioned.

Diagnostic Value of Extracreatinuria—Robert points out that aminoacetic acid has been found helpful in the treatment of progressive muscular dystrophy by a number of investigators. He states that, since it was discovered that creatinuria occurs in many disorders but can be increased by the administration of aminoacetic acid only in cases of progressive muscular dystrophy (so-called extracreatinuria), aminoacetic acid has been used also for diagnostic purposes. Although the author was able to corroborate the favorable action of aminoacetic acid in progressive muscular dystrophy, he gained the impression that the so-called extracreatinuria is not specifically characteristic for progressive muscular dystrophy. He describes a case of hyperthyroidism combined with amyotrophic lateral sclerosis. The examinations for creatine-creatinine revealed a considerable reduction in the total creatinine elimination in the course of an increased creatinuria. Following the administration of aminoacetic acid the creatinuria was increased. The author concludes that the so-called extracreatinuria is not restricted to progressive muscular dystrophy.

- So Called Anaphylatoxin Produced by Kaolin or Starch A Lumière and P Meyer—p 1251
- Piercing Pains in the Side in Children E Nassau—p 1252

Gargling—Haase calls attention to the fact that several authorities have rejected the use of gargles in the treatment of inflammations in the region of the pharynx, not only because it is in direct opposition to the rule that inflammatory processes should be kept quiet but also because it causes pain and the action of the antiseptic fluid is only slight. The author describes roentgenologic studies conducted in order to demonstrate to what extent the gargling fluid comes in contact with the pharyngeal structures. By means of roentgenograms made in the course of gargling with contrast mediums and after contrast visualization of the tonsils, he was able to show that the gargling fluid reaches, under the most favorable conditions, the palatine arch and the upper tonsillar pole but not the tonsils or the posterior pharyngeal wall. He considers this an added reason for dispensing with the use of gargles in the treatment of inflammations in the region of the pharynx.

Calcium Therapy of Allergic Conditions—Kallós and Kallos Deffner cite experiments proving that the efficacy of calcium therapy in allergic conditions is the result of a lessened permeability of the marginal layer of the cells particularly of the capillary walls, and of a reduction of the irritability of the sympathetic nervous system. This explanation was accepted by a number of investigators who had been able to demonstrate that calcium prevents shock. However, the authors point out that the literature reports no studies on the effect of calcium on the antigen-antibody reaction that underlies the allergic condition. Since they had seen favorable effects from calcium therapy in numerous cases of allergy, they decided to give their attention to the antigen-antibody reaction. They made their tests on the isolated horns of the uteri of guinea-pigs that had been rendered allergic to horse serum, and they summarize their observations as follows: 1 Calcium gluconate exerts no harmful effects on the isolated uteri of guinea-pigs that have been sensitized against horse serum, even if it is used in strong doses and for long periods. 2 If specific antigen is added to the uterus horns that contain antibodies the anaphylactic contraction does not develop when calcium is present. 3 That the contraction does not appear is merely a result of a modification of the smooth musculature, for the antigen-antibody reaction,

which otherwise is always accompanied by an anaphylactic contraction of the uteri, takes place unhindered in the presence of calcium gluconate 4 The simultaneous administration of antigen and calcium permits specific desensitization of the uteri without producing an anaphylactic contraction 5 An existing anaphylactic contraction of the isolated uteri can be released instantaneously by the administration of calcium 6 The results of these experiments show that the calcium therapy of allergic conditions is well founded

Modification of Reid-Hunt's (Acetonitrile) Test by Antithyroid Protective Substances—Fellinger and Hochstädt base their studies on the following considerations The administration of thyroxine confers on white mice a considerable resistance to the highly toxic acetonitrile. If the antithyroid protective substance is biologically antagonistic to thyroxine, the simultaneous administration of the antithyroid protective substance and of thyroxine should cancel this protective action, or at least weaken it, so that the acetonitrile would exert its fatal action in spite of the administration of thyroxine In surveying the results of their experiments, the authors find that the various arrangements of the test give more or less the same results, that is, there is a more or less strong antagonistic action of the antithyroid protective substance against the active principle of the thyroid, either in the form of thyroxine injections or by the internal production of thyrotropic hormone However, the action of the antithyroid protective substance was considerably stronger against the thyrotropic hormone than against thyroxine In trying to explain this observation, the authors point out that, although the ether-soluble antithyroid protective substances act on the thyroid hormone, they act even more strongly on the thyroid itself or on its regulatory mechanism (thyrotropic hormone or hypophysis)

Auto-Urotherapy—Krebs points out that auto-urotherapy has been found effective in allergic conditions (hay fever, asthma, migraine, urticaria and so on), in certain spastic conditions and in whooping cough The injection of the patient's own urine is not always effective, as it failed in from 25 to 33 per cent of the cases He thinks that auto urotherapy will remain unreliable as long as there is no method that will indicate the curative value of the urine So far no active substance has been isolated from the urine, but studies have disclosed differences between effective and ineffective urines These studies were concerned with the determination of the acetones and the reductases The author found that the effective urines had reduced amounts of acetone substances and increased amounts of reductases, and occasionally increased amounts of both acetone substances and reductases It was found also that the ferment reactions can be influenced by age, infections, time of day, exercise, massage, sweating cures, starvation and medicaments The advisability of auto urotherapy cannot be determined on the basis of the diagnosis of the disorder alone, the quality of the urine, particularly the amount of acetone substances and of reductases, must also be considered Reduced reductase content together with increased or reduced amounts of acetone substances contraindicates auto-urotherapy

Elimination of Vitamin C in Experimental Nephritis—Pinotti studied the renal elimination of cevitamic acid on guinea-pigs in which nephritis had been produced by the administration of uranic acid or corrosive mercuric chloride The animals were killed during various stages of the poisoning and the kidneys were subjected to histologic examination It was found that the animals eliminate normal amounts of cevitamic acid during the stage of congestion of the glomeruli If the animals are killed when the elimination of the cevitamic acid commences to increase or is at its height, the glomeruli are

no longer in the stage of congestion but the disease is already further advanced Gradually the elimination of cevitamic acid returns to normal values As the increased elimination of cevitamic acid is apparently dependent on the glomerular system of the kidney and as guinea-pigs with scurvy do not exhibit an increased elimination of cevitamic acid during any stage of nephritis, that is, the scorbutic organism with its capillary disturbances does not have the capacity to reduce cevitamic acid, it appears probable that the capillary walls have reducing capacities The author hopes to corroborate this assumption by further experiments

Mycosis of Hands and Feet with Especial Consideration of Mycotic Dysidrosis S Ballagi —p 1204

Focal Infection in Eczema—According to Memmesheimer, an eczema develops if some injurious irritant comes in contact with an organism that is hypersensitive to it This indicates that, in addition to the irritant, the condition of the skin or of the organism is of vital importance The sensitivity of the skin may be congenital or acquired In this study the author gives his attention to acquired sensitivity, which may develop suddenly, after injuries, burns and the like, or gradually In the gradual development, focal infections play an important part The author reports that, of ninety-eight patients with eczema who were carefully observed and examined for the presence of focal infections, eighty-two had focal infections The dental foci were most frequent, then followed in the order of their frequency the foci in the tonsils and the accessory sinuses, the intestinal tract, the urogenital tract, the respiratory tract and various other sites The author states that of seventy six cured patients, in whom the infectious foci had been detected and treated, only ten had a relapse within a year, while of fifteen in whom no focus had been detected, six had a relapse He concludes that a focal infection may have been overlooked in the group of fifteen patients He stresses the necessity of careful observation of each patient and concedes that the treatment is often extremely wearisome and trying He expresses the hope that further studies will reveal that the treatment of other hypersensitivity diseases (including asthma and hay fever) can be benefited by attention to focal infections

Desensitization in Menstrual Intoxication—Geber calls attention to the fact that menstruation in some women is accompanied by so-called menstrual exanthems These cutaneous changes appear in various forms, as papules, herpes blisters, erythemas, urticaria or even pemphigus-like eruptions These manifestations have in common that they are of an inflammatory nature and that they appear and disappear with the menstruation They are frequently accompanied by general indisposition, severe, uncontrollable headaches, vomiting, convulsions, articular pains and other conditions, but these general manifestations may also be mild or entirely absent On the other hand, the general symptoms may exist in the absence of cutaneous lesions The author points out that in former studies he has demonstrated experimentally that all these symptoms, the general as well as the cutaneous, are due to the fact that certain substances for which these women have a hypersensitivity enter into the blood stream during menstruation For instance, when he injected the serum withdrawn during an attack of menstrual urticaria into the same woman during the intermenstrual period an urticarial eruption resulted The serum that had been withdrawn during the intermenstrual period or several days before the onset of the menstruation did not have this effect Moreover, the serum from one woman did not produce urticaria in other women, nor did the serum from other women elicit an urticaria in the woman who was subject to menstrual urticaria The author points out further that, in collaboration with another

investigator, he has proved that menstrual herpes is an allergic condition. Reasoning that the various disorders that concur with menstruation might be of an allergic nature, he decided to try desensitization. For this purpose he employed the serum of each patient, which had been withdrawn during the most severe stage of the disorder. The blood was withdrawn under sterile conditions, centrifugalized and conserved with several drops of a 0.3 per cent solution of phenol. The serum prepared in this manner could be kept for several months without losing its efficacy. During the intermenstrual period the patients were given twice daily at two sites intracutaneous injections of from 0.2 to 0.4 cc of the serum. The injections were always made at the same sites, usually on the back. After eight or ten injections the sites were changed. In some cases, desensitization was accomplished after from twelve to fourteen injections, that is, during one intermenstrual period, while in others two or three series of injections were necessary. In two women relapses occurred after nine and eleven months, respectively, but renewed desensitization was again effective.

Demonstration of Metastases of Chorionepithelioma

—Stockl reports that the biologic test of the urine according to the method of Aschheim-Zondek has proved to be a reliable control method, which indicated the presence of living and growing chorion tissue in the organism and thus determined the prognosis of the case observed by him. The positive outcome of the Aschheim-Zondek reaction fifty-seven days after the combined radium and roentgen irradiation led to the discovery of numerous pulmonary metastases in the roentgenogram. In spite of the application of large doses of roentgen rays and of additional radium irradiation, the microscopic examination of the uterine mucous membrane disclosed tumor tissue in the form of vascular infiltrations. The author points out that these anatomic observations indicate the great resistance of the chorion cells against radiant energy particularly roentgen rays. He concludes that the combined application of radium and roentgen rays in cases of intra-uterine chorionepithelioma may be considered a radical method of treatment only if large doses of rays are applied.

Pathogenesis of Spasmophilia G O Harnapp—p 262

*Local Insulin Lesions During Childhood A Schlüter—p 303

Triangular Shadow in Right Upper Part of Thorax in Nurslings—Yamaoka and Nakaya report that they observed a peculiar shadow in the roentgenogram of the thorax of two nurslings. The shadow covered a small triangular space in the right upper pulmonary field. In the first nursling, a girl aged 8 months, a troublesome cough had existed six weeks previous to hospitalization. In spite of many therapeutic measures, the shadow remained unchanged for six months. Finally, in view of a positive Wassermann reaction, antisyphilitic treatment was instituted and after that the pulmonary shadow decreased in size. The second case concerned a nursling aged 10 months, who at the time of the discovery of the triangular shadow had had a bronchitis of one week's duration. The shadow increased gradually until it reached the apex and then remained stationary for four months. After that a massive shadow developed in the middle and lower sections of the right side of the lung. Following an attack of measles, the massive shadow disappeared and a honeycombed outline appeared in its place. The necropsy revealed infiltrations in the right upper and lower lobes and massive postmorbilious bronchiectasis formation. The authors mention several factors that might possibly cause such shadows (atelectasis infiltrations mediastinal

pleurisy, hypertrophy of the thymus and stasis in the superior vena cava) and point out that the necropsy in the second case indicated that a pneumonic infiltration had caused the shadow. Since in the first case the shadow responded to antisyphilitic treatment it is possible that the shadow was caused by some syphilitic process either outside or within the lung. The authors concede that their observations are insufficient to arrive at a definite conclusion regarding the origin of such shadows.

Local Insulin Lesions During Childhood—Schlüter calls attention to the fact that prolonged insulin therapy may result in atrophy or in hypertrophy of the subcutaneous fat tissue at the site of injection. Atrophy is the most frequent form. He reviews the literature on this form, mentioning the various etiologic explanations that have been suggested, and then states that he himself observed this atrophy of the subcutaneous fat tissue in a girl, aged 11, who had had severe diabetes since the age of 5. The child had depressions at the sites of injection on both thighs. Moreover, the subcutaneous tissues were hardened and small infiltrates were palpable. The fat tissue had completely disappeared in these regions. Then the author states that circumscribed hypertrophy of the fat tissue is extremely rare. After citing several cases from the literature, he describes two cases of his own observation. The first concerned a boy, aged 7, who had received antidiabetic treatment since his third year. After three years of treatment he exhibited on both thighs at the sites of injection a cushion-like elevation of the skin. In spite of alternation of the sites of injection, the swellings remained. The second case observed by the author was that of a girl, aged 13, who had received insulin injections for the last thirty months. The swellings that had developed at these sites disappeared gradually in the course of nine months after the sites of injections had been changed. The reason why in some cases there results an atrophy and in others a hypertrophy from insulin injection has not been definitely explained as yet. The author thinks that the term "lipodystrophy," which was first applied by Depish to the atrophic form, can be applied also to the hypertrophic form.

Combined Serotherapy and Chemotherapy of Lobar Pneumonia—Stein employed the combination therapy by administering a protein-deficient, highly active polyvalent pneumococcal serum which is directed principally against the pneumococci of types I and II, and an injectable 20 per cent solution of quinine. He describes six cases in which he used this combination therapy with good success. In surveying the effects his attention was drawn to two factors: (1) the critical defervescence before the seventh day and the consequent early detoxication of the patient, and (2) the fact that, in spite of the early defervescence, the pathologic anatomic course developed in the usual manner. In answer to the question whether the results he obtained are actually ascribable to the combination therapy, the author cites investigators who obtained favorable results with the use of quinine injections and others who found serotherapy effective, but he also cites factors which indicate that in his cases the good results were caused by the combination therapy. He points out that the advancement of the pathologic anatomic process in spite of the early defervescence was also noted by the observers who found quinine therapy or serotherapy alone effective. He advances evidence that the manner of application of the serum and the quantity of quinine are important. He observed that, when the intramuscular injection of the serum failed to accomplish the desired results, the intravenous injection was effective. He says that the daily dosage of quinine should not be less than from 1 to 1.5 Gm.

Congenital Cystic Kidney and Blood Pressure—Willer reports the clinical histories of five patients with congenital cystic kidney. All patients reached a comparatively high age (53 to 65), which is important for the estimation of possible circulatory effects of the renal disturbance. The author studied these cases carefully in order to find an answer to the question: Is there a nephrogenic hypertension? He points out that in the patients whose circulatory organs were free from pathologic changes no increase in blood pressure had been found in the course of a prolonged clinical observation, although the rest nitrogen values were rather high. He calls attention to his former studies on cases of amyloid contracted kidney, congenital renal defect and contracted kidney, in which he proved that the various theories regarding the renal origin of hypertension did not withstand criticism, and he shows that these cases of congenital cystic kidney bear out the same conclusion. He reasons that, if such extensive exclusion of renal tissue and the consequent accumulation of waste products produce no increase in blood pressure, it appears unlikely that much less extensive parenchymal impairments, observed in secondary inflammatory or in true vascular contracted kidney, should do so. The author believes that the interrelations between renal damage and hypertension must be of a different nature, assuming that in case of concurrence of renal defect and hypertension the latter is either the primary condition or is a coordinated process.

Limitations and Dangers of Fasting Cures—According to Eisenberg, fasting is a valuable therapeutic method or at least a therapeutic adjuvant. He found that fasting is of great help in some acute infectious diseases, high blood pressure, bronchial asthma, eczemas, gout, rheumatic disturbances, gastrointestinal disturbances and obesity. However, he stresses that the fasting cure has limitations and may involve danger. Its indiscriminate use by lay persons is inadvisable. He also warns physicians against using the method carelessly. Fasting should never be instituted unless a definite diagnosis has been made. Patients with cancer should not fast because of the tendency to cachexia. In pulmonary tuberculosis fasting is inadvisable since it may lead to reactivation. However in tuberculosis of other organs, fasting has been known to be helpful. In patients with diabetes, fasting counteracts the glycosuria, but this improvement is only temporary, for the sugar elimination usually returns when food is taken again. Occasionally a fasting cure is followed by an increase in the tolerance and furunculosis, gangrene and increased blood pressure, which frequently appear as sequels of diabetes, are favorably influenced by fasting. Hysterical patients should never be subjected to a fasting cure, and most mental disturbances, particularly manic psychoses and paranoia, contraindicate fasting cures. In exophthalmic goiter, fasting may be tried only if the patient is obese. In severe myocardial disturbances fasting is inadvisable, but it may be tried in the milder forms and it must be interrupted at the first unfavorable signs. In uterine myomas fasting has been advised by some, but the author saw no favorable effects from fasting in this condition, neither did his observations corroborate the suggestion that a fasting cure is helpful in stimulating a poor appetite; in fact, he warns against subjecting emaciated neurasthenic patients who lack appetite to fasting cures even if they are subject to constipation, which ordinarily is considered an indication for a fasting cure. Chronic gonorrheal arthritides are refractory to fasting, although many other forms of arthritides react to this treatment quite favorably. The management of a fasting cure requires conscientious supervision. Especial attention must be given to the heart. Although patients with valvular lesions and with coronary sclerosis tolerate the fasting cure quite well, it is important to give proper attention to the cardiac function of patients with rheumatism, tonsillitis, inflammation of the renal pelvis, or syphilis. If myocardial disturbances appear in such patients, the proper medication and bedrest should be instituted at once and, if the pulse rate remains 120 or higher for several days, the fasting cure must be interrupted. The author is unable to make definite statements regarding the duration of a fasting cure, but he thinks that they should last longer than four weeks only in rare instances. The diet at

the end of the fasting cure should be adapted to the individual case, for, although fruits may be advisable in the obese patients with a tendency to constipation, patients with gastro-intestinal or biliary disorders would require a blander diet.

*Treatment of Epilepsy with Antirabic Vaccines. M. Nikolic—p. 1493

Treatment of Perforating Gastric and Duodenal Ulcers—Von Haberer shows that, in the treatment of gastro-intestinal ulcers that perforate into the free abdominal cavity, strict adherence to a certain surgical method is no longer justified. The chief concern should not be the choice of the intervention but the coping with the dangerous results of the perforation in a manner that takes account of the conditions existing in the individual case. As the chief aim must be to preserve the endangered life, it will often be necessary to be satisfied with simple sewing over, and any reflection as to whether this intervention will be permanently adequate will have to be given up. However, the author thinks that there is a considerable number of patients in whom, in consideration of the still favorable circulatory conditions (good blood pressure and so on) it is permissible to resort to resection in spite of the perforation and generalized peritonitis. In these cases resection is preferable because it not only blocks the source of the peritonitis but also removes the focus as such and, if done as a large resection produces conditions that, on the basis of present-day knowledge, are most likely to prevent a recurrence of the ulceration. If the cases are well chosen the resection produces favorable immediate as well as permanent results.

Psychic Moods and Acid-Base Equilibrium—Hoff cites instances in which, as the result of the experimental alteration of the acid-base economy, there appeared changes in the psychic mood. He observed that an acidotic alteration resulted in a depressive mood. Moreover patients with a diabetic acidosis often are ill tempered and depressed, even if there are no disturbances in the consciousness. Psychiatrists know that anxiety, fear, hallucinations and paranoid disturbances appear during the precomatose period. The author thinks that the psychic disturbances that develop during the menstrual period may likewise be connected with the acidotic alteration in the metabolism that exists at the onset of the menstrual period. In this connection he calls attention to the high incidence of suicides during this period. He points out that an acidosis exists during the febrile stage of infectious diseases, when the patient is usually depressed, whereas the period of convalescence, when the patient is in a more cheerful mood, is characterized by an alkalosis. He concedes that the complicated interconnections of the sympathetic regulations doubtless play a part in these psychic processes and that the changes in the acid-base economy are only a link in these complicated interrelations, the glands of internal secretion and the mineral economy of the organism also playing important parts. Nevertheless, he thinks that his observations throw more light on the difficult problem of the interrelations between somatic and psychic processes.

Treatment of Epilepsy with Antirabic Vaccine—In reply to an inquiry as to whether it would be permissible to administer antirabic vaccine to an epileptic patient who had been bitten by an apparently healthy dog, Nikolic advised not only the usual dose but also a certain dose of the stronger, cerebral type of antirabic vaccine in order to test the effect on the epilepsy, a measure that had been suggested by several institutes. On three successive days the patient was given one ampule each of the prophylactic antirabic vaccine and on the six succeeding days one ampule each of the stronger antirabic cerebral vaccine. During three months following this treatment he did not have an epileptic attack, although formerly he had attacks sometimes twice daily. His psychic and somatic condition has considerably improved. He feels well and is able to work. The author thinks that it cannot be doubted that this

improvement in the epilepsy is causally related to the administration of the antirabic vaccine. He points out that the therapeutic success is probably chiefly due to the endotoxins of the fixed virus. He thinks that the antirabic vaccine may be used with hope for success in all forms of epilepsy that are not the result of a trauma during extra-uterine life or of tuberculous disease.

Allergy in Diphtheria—Siegl shows that, concerning the nature of immunity in diphtheria, the opinion predominates which considers it a purely antitoxic process. However it is nevertheless probable that there are other possibilities of defense against diphtheria in addition to the formation of antitoxin. Observations by the author and by Hamburger on the immunobiologic behavior of twenty children who recovered from diphtheria spontaneously disclosed that in three fourths of these cases cure resulted without the appearance of demonstrable quantities of antitoxin in the blood. These observations indicate that the organism does not require antitoxin formation even in case of active invasion by diphtheria bacilli. The author points out that similar observations were made by Rosling and thinks that efforts should be made to detect the factors that, in the absence of antitoxin, are responsible for this defense against infection with diphtheria bacilli. The possibility of an allergization has been considered repeatedly by earlier investigators. In this connection the author calls attention to observations made by Behring and Haymann and to the so-called pseudo-reaction that occasionally develops in case of the diphtheria toxin reaction according to Schick. It was assumed by some that the pseudoreaction is the manifestation of a specific sensitization. Later, this pseudoreaction was regarded as being in causal relationship with tuberculosis or tuberculin sensitivity. The author concluded that the pseudoreaction in the Schick test is not of uniform origin but that it may be of specific as well as of nonspecific origin, that is, it may be caused by a former contact with diphtheria bacilli or by various nonspecific factors. He describes tests made on persons with positive and negative tuberculin reactions, studies on the specificity of Zoeller's antitoxin reaction and observations made in the course of inoculations with Löwenstein's prophylactic diphtheria ointment. He concludes that the existence of a specific diphtheria allergy within the scope of the general defense against diphtheria cannot be doubted. He thinks that diphtheria immunity comprises a complex of different defense mechanisms, of which only certain ones can be detected as yet.

Aleukemic Myelosis with Aspects of Panmyelophthisis—Henschen and Jezler report the clinical history of a man, aged 56 in whom, although the clinical aspects corresponded to those of hemorrhagic aleukia the pathologic anatomic aspects indicated the opposite, that is, a hyperactivity of the blood-forming organs. As an aleukemic myelosis the case likewise takes a unique position, because during a long period of obser-

vation the circulating blood never contained preliminary myeloid forms. Moreover, the results of splenectomy in myelosis could be watched for a considerable length of time. The authors think that, although such cases have not been reported as yet, they probably are not as rare as might be assumed. However since the qualitative and quantitative inhibition of the transfer of leukocytes between the site of formation and the peripheral circulation is nearly always accompanied by a corresponding one of the erythrocytes and thrombocytes, such disorders were generally diagnosed as aleukia, aplastic anemia or panmyelophthisis, and it was overlooked that the presence of tumors of the spleen and the liver does not fit into the symptomatology of these disorders. In such disorders, it is advisable to think of the abnormal "panmyeloparetic" forms of leukemia. The relations between leukemia and aleukemia are often closer than may be expected on the basis of the nomenclature. To be sure, if complicated methods of examination cannot be employed, only a probability diagnosis can be made. It is possible, however, that further improvement of the functional tests might better the prospects for a more exact diagnosis. The authors point out that the flooding out of the blood cells from the blood-forming organs or the inhibition of this process is still problematic and that, until this problem is understood, all conclusions regarding the state of the bone marrow which have been arrived at on the basis of the peripheral blood picture, will remain unreliable.

Influence of Liver Extract on Cholesterol Metabolism

—Schally demonstrates that parenterally administered liver extract normalizes the reduced as well as the increased cholesterol content of the serum. He concludes from this that the liver plays an important part in the cholesterol metabolism. The functional disturbance of the liver, which presumably exists in case of abnormal cholesterol metabolism and which probably is a causal factor in the pathogenesis of true lipid nephrosis, can be largely compensated for by the administration of liver extract and thus the essential symptoms of nephrosis can be counteracted. It is assumed that an endocrine function of the liver effects this metabolic regulation.

Thyroid and Cholesterol Metabolism—Schally investigated the cholesterol metabolism in disturbances of the thyroid function, particularly in hyperthyroidism. He found that the cholesterol content of the serum is reduced in the majority of cases of hyperthyroidism. The more severe the disturbance the lower the cholesterol value. All therapeutic measures that produce an improvement in the hyperthyroidism also increase the cholesterol content. This increase is especially noticeable following strumectomy, in which case the cholesterol value often increases above the normal value. The author considers it possible that there is a causal connection between the reduction in the cholesterol content and the general symptoms of hyperthyroidism. He says that, if liver extract is administered without regard to the thyroid, an increase in the cholesterol content can be effected, and this increase is accompanied by an improvement in the general symptoms. To be sure, the reduction in the cholesterol content exists not only in cases of hyperthyroidism but also in other disorders of the thyroid that are not accompanied by an increase in the basal metabolic rate. The author differentiates between qualitative and quantitative dysthyroidisms. Whereas the basal metabolic rate is only an indicator of the quantitative dysthyroidisms, the reduction in the cholesterol content exists in both types of dysthyroidism. The author concludes that the thyroid exerts an inhibiting influence on the cholesterol metabolism.

Pulverized Colon of Hogs in Treatment of Pernicious Anemia

—Schemensky discusses aspects that induced him to resort to the administration of pulverized colon in cases of ulcerative colitis reasoning that the anemia developing in the course of this disorder is the result of the severe changes in the colon and that a substitution therapy might influence the condition favorably. However the author did not have a sufficient number of cases of ulcerative colitis to permit a definite conclusion regarding the value of this treatment. Later he decided to try pulverized colon in the treatment of pernicious anemia, and in all twenty cases in which he tried this treatment he obtained the same results that are observable following treat-

ment with liver or with stomach preparations. The improvement in the blood picture was perhaps somewhat slower than in the case of liver and stomach preparations, but the subjective improvement was about as rapid and was already noticeable before the blood picture had improved. The myeloid complications, from the slightest paresthesias to the severest disturbances in walking, were greatly improved. The preparation was produced from hog colon by drying in the vacuum and was defatted by means of petroleum ether. The preparation has an agreeable flavor, and the patients take it in bouillon without objection. The average dose is one teaspoonful five times a day. The minimal dose is one teaspoonful three times a day and the maximal dose is two teaspoonfuls five times a day. The author states that another clinic has used the colon preparation with good success in the treatment of pernicious anemia. He also makes suggestions regarding the probable mode of action of the preparation.

 Bilateral Ureterovaginal Fistula Implantation into Bladder Seven and Eleven Months After Injury E. von Graff—p 2110

Vesicovaginal Fistula of Rare Etiology—Ljubimow states that the vesicovaginal fistulas are rarely caused by coitus and cites a report indicating that among 448 cases only one was caused in this manner. He says that according to Knauer's statement these injuries are most frequently longitudinal tears in the posterior wall of the vagina or in the posterior vaginal vault. Injuries of the anterior vaginal wall are comparatively rare and injuries of the wall of the urinary bladder are extremely so. The author reports the clinical history of a woman who, for ten years, since her first coitus, had had urinary incontinence. The anamnesis revealed that the first coitus had been extremely painful and followed by bleeding and involuntary discharge of the urine. The physician who was consulted at this time made no gynecologic examination and, since no other medical aid was requested, the urinary incontinence persisted for the following ten years. Then she was admitted to the author's clinic and the examination disclosed at the site at which the anterior vaginal wall adheres to the cervix uteri a fistular opening measuring two and one-half fingerbreadths. The fistula was repaired and the involuntary discharge of the urine ceased. Sexual intercourse was not resumed until cicatrization had been completed, but, after that, coitus caused no pain and the fistula did not reopen. This case is noteworthy not only because of the etiology, localization, size and duration of the fistula, but also because it must be assumed that during the ten years of the duration of the fistula coitus took place through the fistula into the urinary bladder. This explains the bleeding at every coitus and the subsequent pains in the lower part of the abdomen.

- Hormone Therapy of Menstrual Disturbances and Its Theoretical Foundations A Westman—p 233
 *Difficulties During Dorsal Position in Pregnant Women G Ahltop—p 295

Difficulties During Dorsal Position in Pregnancy—Ahltop reports the history of a woman, aged 23, who during the last half of her first pregnancy experienced the following symptoms when lying on her back: increase in the pulse rate, reduction in the blood pressure and pulse pressure, difficulty in breathing and a feeling of discomfort and tension in the upper part of the abdomen. Roentgenoscopy revealed a reduction in the volume of the heart. A series of examinations disclosed that these symptoms developed only when the pregnant uterus rested against the right posterior part of the peritoneum. A survey reveals that during pregnancy, particularly during the latter half, there exists an increased predisposition for circulatory disturbances, and experiments on animals disclosed that

compression of the inferior vena cava causes reduction in the blood pressure and increase in the pulse rate. The author thinks that the symptoms in the described case (and in one previously reported) may be explained by the fact that the pregnant uterus compresses the vena cava more or less completely and probably pushes the diaphragm upward at the same time. In this connection he investigated the symptoms commonly present when pregnant women assume the dorsal position and also the spontaneous changes in the sleeping position during the second half of pregnancy. He found that of 653 pregnant women 197 (30 per cent) had some symptoms when lying on the back (pains in the abdomen or back, stronger movements of the fetus, palpitation and so on). In forty-two women (64 per cent) lying on the back was impossible, and more than one third of pregnant women changed their sleeping position during the second half of pregnancy. In another group of 189 patients it was found that in almost all cases the symptoms disappeared completely after parturition. The author points out that there is a parallelism between the fairly common feelings of discomfort and the grave symptoms exhibited by the patient whose history is described.

Pathologic Changes in Spinal Cord in Pernicious Anemia and Cancer Metastases—In Einarson's patient, a woman aged 58, with marked pernicious anemia and myelopathy for five years, objective symptoms of gastric cancer set in one year before death, an exanthem appeared in the lumbar region eighteen days before death and developed into a typical hemorrhagic herpes zoster. There were more or less marked pathologic changes in the spinal cord, and attention is called to the pronounced antagonism between the Nissl elements and the lipid pigment substances. In most of the ganglia examined both normal cells were seen and cells showing general chronic changes (lipoid degeneration, secondary vacuolization, atrophy and nuclear pyknosis). Cancer metastases were located in the four ganglia from the eleventh dorsal to the second lumbar vertebra, corresponding to the extent of the herpetic eruption, and in these ganglia there were not only general chronic changes in all the cells but also toxic vacuolization and coagulation necroses. The general chronic changes are ascribed mainly to the pernicious anemia and possibly in part to a general intoxication from the gastric cancer, the grave acute changes limited to the four ganglia are attributed to the direct influence of the cancer metastases in the ganglia.

 Treatment of Restricted Rotation of Hand After Poorly Healed Fractures of Radius R Ingebrigtsen—p 963

Vitamins A and D in Liver of the New-Born—Toverud and Ender found a variation of from 0.2 to 517 blue units per gram of liver in the vitamin A content of the liver in ninety-seven new-born infants, the average value in the forty-seven premature infants being 47.6 and in the fifty full term infants 28.8. The highest values occurred in the cases in which the mother's diet during pregnancy had had the highest carotene and vitamin A content. Tests of the vitamin D value in forty-four cases showed completely negative results in twenty-four smaller amounts in fifteen and larger amounts in only five in these five there had been abundant vitamin D in the mother's diet during pregnancy.

MATERNAL MORTALITY AND MORBIDITY

CANADIAN CHAIRMAN'S ADDRESS

JOHN R FRASER, M.D.
MONTREAL

The meeting this year is one of peculiar importance, marking as it does the first occasion on which these two great national medical associations have met in joint session. These are anxious times, great problems of economic and social import are in process of solution, and much thought is being expended on the development of schemes for social betterment. It is only natural that some reflection of these activities should be manifested in the proceedings of these meetings.

The world over, if one may judge by published reports, there is an awakening to the fact that obstetrics has failed to keep pace with the progress attained by other branches of medicine in lowering the death rate.

Eardley Holland,¹ recently addressing the Royal Sanitary Institute in London, put the situation fairly before the country when he said:

The failure of the mortality rate to yield one decimal point to the sustained attack which has been directed against it, but its tendency rather to react in the opposite direction, has endowed it with an air of mystery and malignity. The 1933 figure of 45 deaths per 1000 births is 7 per cent higher than the figure for the preceding year, and 15 per cent higher than that of twenty years previously. There is nothing obscure about maternity mortality. Its etiology both in principle and detail is well known, and the way it can be remedied is, to a certain section of the medical profession at all events, perfectly clear. There is no lack of knowledge, but only an obstinate neglect of the application of known facts.

These are the words of one of England's greatest obstetricians.

In order to approach this great problem from as broad a point of view as possible, it is well to familiarize oneself with the situation as it is known to exist.

A remarkable array of reliable information has recently become available for this study. Reports by government departments, medical bodies and private agencies have been presented. Four outstanding documents deserve special emphasis:

1 The report of the Children's Bureau, United States Department of Labor.²

2 The interim and final reports of the Departmental Committee of Maternal Mortality 1930-1932 of the British Ministry of Health, London.

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1935.

¹ Holland, Eardley. *Lancet* 1: 973 (April 27) 1935.

² United States Department of Labor. Children's Bureau publication.

3 The Canada Year Book, 1932.

4 The report on Maternal Mortality in New York City, New York Academy of Medicine, 1933.

The United States Children's Bureau analyzed all the maternal deaths occurring in thirteen states for 1927, and in the same states with the addition of two others for 1928. The states in question are well distributed geographically and may therefore be considered representative of the country at large. In these states during the period reviewed the deaths of 7,537 women were assigned to puerperal causes by the United States Bureau of Census, in accordance with the international list of causes of death. This number of deaths was 26 per cent of the 29,298 deaths from puerperal causes in the entire United States birth registration area for two years. As there were 1,176,603 live births in these thirteen states during this time, these 7,537 deaths gave a maternal mortality rate of 64 per 10,000 live births. One third of these women had not advanced to the third trimester of pregnancy.

The detailed causes of death are shown in chart 1. That 40 per cent of all the deaths were of women who had such obvious and unmistakable signs of sepsis that there could be no question as to how they should be classified shows clearly the serious condition presented by this cause of maternal death.

In the report of the registrar general for England and Wales, as quoted by Bonney,³ it is clear that the death rate directly and indirectly attaching to pregnancy and labor has unfortunately changed very little in the last seventy years.

Hon. Neville Chamberlain set up a departmental committee of the ministry of health in 1928 to study and bring in a report on maternal mortality and morbidity in England. This final report was returned four years later, in 1932. The basis of the report was an investigation into the actual circumstances of a large number of maternal deaths, an enquiry never before attempted on so large a scale. In all, 5,805 cases were investigated. It was found advantageous to classify these cases into two great groups:

Class 1 Deaths directly due to child bearing.

Class 2 Deaths due to an independent cause concurrent with pregnancy or childbirth in which child bearing contributed to or accelerated death or was present merely as an incident.

In Canada, for example, in 1930 there were 243,495 live births with a total mortality of 1,405, a rate of 58 per thousand live births, a similarly high maternal death rate.⁴ In a footnote in the Canada Year Book of 1932 there is the significant statement that, as compared with 1929, the number of maternal deaths shows an increase of sixty-eight, or 51 per cent, for

³ Bonney, V. *Roy Soc (Sect. Obst. & Gynaec.)* 12:75 (July) 1919.

⁴ Canada Year Book 1932.

1930 The chief causes given are puerperal septicemia, albuminuria and convulsions, puerperal embolism, and sudden death in the puerperium

What is true of the country at large can readily be shown to be true of any individual section or community in it, for example, the report of the maternal mortality

Chart 1—Maternal mortality rates by cause and by trimester of pregnancy

in New York City as prepared by the New York Academy of Medicine for the years 1930-1932 When analyzed in the light of a causative factor underlying each death it is seen that the following conclusions may be drawn, as emphasized by the New York group in the summary

- 1 The inadequacy of antepartum care
- 2 Lack of appreciation by those concerned of the gravity of apparently mild symptoms
- 3 The high incidence of operative intervention, more than 45 per cent of the series
- 4 The selection of the wrong treatment or ill advised therapy
- 5 The high incidence of cesarean section and its death rate
- 6 Medical incapacity

Obstetric practice, generally speaking, has undergone much change in the last thirty years At the present time many women exhibit a willingness, even an eagerness, to have their babies born in a hospital At the same time it is true, and will be for a long time to

Chart 2—Deaths primarily due to pregnancy at the Royal Victoria Hospital

come, that the large part of midwifery practice will be conducted in the home This basic fact must always be remembered in any study of maternal mortality

It is true that in many instances this is perfectly safe, provided conditions in the home are reasonably good and favorable, but the case which in the antepartum period can be recognized as abnormal should be handled in the hospital The results of home obstetrics

are not widely known, for accurate figures are not easily obtainable It is possible, however, to derive some such knowledge through the study of reports of the outdoor service of maternity hospitals and the large nursing services, such as those which exist in England

In an effort to answer this question, Thomas Eden⁵ published the tabulated results of the Queen's Institute of District Nursing These midwives, who work not privately but for county nursing associations, attend large groups of women in different parts of the country It will be observed that their mortality rate is less than one half of the national rate The most striking feature, moreover, is the low mortality from sepsis, less than one fourth of the national sepsis rate

The report on maternal mortality in the city of Aberdeen for 1918-1927⁶ is of interest in this regard In domiciliary practice the mortality in the midwives' practice was 1 per thousand births and in that of physicians, 17 per thousand births, while in institutions it amounted to 4.5 per thousand births At a first glance these figures would seem to support the contention that home delivery was decidedly safer than institutional and that midwives were safer than physicians That this is not the case, however, is readily seen when it is realized that in all serious or abnormal conditions the patients are transferred to a physician or sent to the hospital

Institutional practice, though handicapped in many communities by being compelled to deal with all types

Chart 3—Deaths not primarily due to pregnancy at the Royal Victoria Hospital

of emergencies, can equal or improve on the statistics of home service The East End Maternity Hospital in London maintains a joint outdoor and indoor service. For the period 1925-1929 the exceedingly low death rate of 0.48 per thousand births was recorded

During the period 1906-1934 in the Royal Victoria Maternity Hospital, Montreal, there were in the combined outdoor and indoor delivery services 48,752 confinements with a total of 246 maternal deaths, a rate of 5 per thousand deliveries These deaths were divided into two great groups (1) those due primarily to pregnancy and (2) those not primarily due to pregnancy These results are of more than usual interest when it is considered that 38 per cent of the cases admitted were emergencies One hundred and two of the patients were primiparas and 124 were multiparas

The influence of age on mortality is clearly shown in table 10

Operative delivery was necessary in 73 per cent of this series

In this study no special attention will be directed to the influence of abortion as a causative factor, although

⁵ Eden, Thomas Brit M J 1 399 (March 11) 1933
⁶ Aberdeen Report Scottish Board of Health 1928

one realizes the increasingly large part it is playing in every country in swelling the mortality tables

It is difficult in every case to track down the actual cause of death, as one frequently finds more than one influencing factor, however, in all summaries three groups of conditions seem preeminently responsible, namely, sepsis, toxemia and hemorrhage, acting either singly or in combination. A better appreciation of the importance of the recognition of the early manifestations of toxemia and hemorrhage, together with the institution of more active therapy, will in the future do much to lessen the dangers of these two conditions.

The problem *par excellence* awaiting solution is, however, the matter of infection, puerperal infection including under that term septicemia, pyemia, phlebitis and all its other manifestations. Undoubtedly the figures would be even higher if they included all cases in which bacterial invasion of the birth canal determined the final issue. Again, often in the lists of

TABLE 1—Maternal Death Rate in England and Wales, 1848-1917

conditions not directly due to, but associated with, pregnancy, such conditions as pneumonia may, though classed separately, frequently be but a conspicuous part of a sepsis. Embolus is often a part of a mild pelvic sepsis.

In the section on puerperal sepsis in the ministry of health report one reads that it is widely held that puerperal sepsis occurs more frequently in maternity hospitals than in domiciliary practice. This is a natural survival from the days when epidemics in institutions were common and of alarming magnitude. It gains weight from the fact that major obstetric difficulties are dealt with in hospitals and naturally carry a high death rate from infection. Unfortunately the Aberdeen report of 1928 gave some support to this contention. There is definite evidence, however, to show that the majority of septic deaths do not occur in epidemics but rather in an isolated or sporadic fashion. Even more important is the conclusion drawn in the British report that the occurrence of sepsis after normal labor is no greater in the hospital than in the home.

When due attention is concentrated on these predominant sporadic infections and on the incidence rather than on the death rate (which is apt to be influenced by other factors), the case bears a different aspect. In three large centers of maternity work, viz., Queen Charlotte's Hospital, the Elsie Englis Hospital

in Edinburgh and University College London, it has been the custom for the last two or three years for all pyrexial cases occurring in the hospital or outpatient practice to be bacteriologically investigated as soon as they occur. In each center it has been found that the incidence of infection by hemolytic streptococci has been consistently higher among the women delivered at home than among those delivered in hospitals, and that in spite of the fact that in the "district" only normal booked cases are dealt with, whereas in the hospital "emergency" and abnormal deliveries are also undertaken, and an opportunity for contagion is frequently present.

While, therefore, the committee is fully alive to the threat of contagious infection in maternity hospitals

and would emphasize the need for constant vigilance and improved methods of avoiding it, it takes the view that this is not the outstanding cause of infection by *Streptococcus haemolyticus* or of septic infection following normal labor.

Again the British report emphasized the very significant fact that 20 per cent of all deaths follow a normal labor. If these infections were brought to the genital tract of the women during or after labor, as is

probable in the light of recent research, it is a very significant fact, for it means that much of it can and should be avoided

In the past these organisms were regarded as having been preexistent in the birth canal or transferred there by the attendant from other cases. Doubtless on occasion this happens, but is it by any means the common occurrence?

Taylor and Wright,⁷ in an examination of the vaginal flora of 1,123 women, found *Streptococcus pyogenes* in only 3 per cent during labor, and fever developed in less than one in ten of these. A similar finding is reported by Rose.⁸

Colebrook⁹ is of the opinion that *Streptococcus pyogenes* causing puerperal infection is not present to any extent in the vagina during labor. In a critical investigation of the bacterial flora in the vagina of 855 women examined before delivery, thirteen strains of *Streptococcus haemolyticus* were isolated, only four strains were found complying with the usual tests as applied to known human infections. This reduces the incidence to 0.48 per cent. He concludes with these words: "The vast majority of severe puerperal infections by hemolytic streptococci have been conveyed to the genital tract during labor or after delivery and were not present before delivery."

It is of the greatest interest that by the work of Kanter and Pilot,¹⁰ Paine of Sheffield, and Smith¹¹ of Aberdeen it has been clearly proved that, in cases of puerperal sepsis investigated bacteriologically by them, infection was shown to have occurred by droplet infection from the nose and throat of those in attendance at the time of confinement.

| Extrapuerperal causes | 344 | 16.9 |

It is known that infections have occurred when people with beginning throat infection were in attendance at labor or when the patient herself had a respiratory infection. Often in the routine culture of the throats and noses of interns and nurses a pure

culture of streptococcus is demonstrable. It is therefore evident that there may be several sources, such as the woman herself, her husband, or a nurse or physician attendant at the labor.

Another aspect of the problem is clearly fundamental and ultimate, viz., the standard of health and physical capacity of womanhood, which may be favorable or

unfavorable to normal pregnancy and childbirth. One cannot expect a low maternal mortality rate unless the women subjected to the strain and stress of the function of childbirth are themselves healthy and physically fit to undergo it, this consideration must in the long run exert a profound influence on the whole question. Rickets in childhood, tuberculosis, occult nephritis, anemia in young women, rheumatic fever, venereal disease, malnutrition or focal sepsis are serious factors. At no time in the present century have the dire effects of malnutrition been witnessed more clearly than in the past four years.

Considerable emphasis must be placed on the existence or not of toxemia, the general conduct and length of the labor, the time of rupture of the membranes, the amount of handling, the associated trauma, the blood loss and the amount of fatigue or exhaustion that is the result.

Although many men believe that vaginal examinations if carefully carried out offer little risk and are distinctly preferable to rectal examinations as a means of following the course of labor, I believe that as a general rule the consideration of the vaginal canal as a closed cavity throughout labor and the use of rectal examinations as a substitute have been distinct advances in the conduct of ordinary labor. After all, the careful study of a woman up to the time of labor should in the vast majority of cases preclude the necessity for much internal examination.

Of the many contributory factors that influence the development of sepsis, the rising incidence of operative intervention for one reason or another, with the course of labor constitutes one of the greatest of problems—"the prophylactic forceps and cesarean section."

Platt¹² of Iowa, in a masterly report to the White House Conference in February 1931, drew attention to the importance of this question. After showing conclusively the injurious effects on both mother and child of unwise operative intervention with labor, he

concluded with this powerful statement "But for permanent and lasting relief a return to first principles is necessary. It should be taught that any interference with normal labor constitutes a definite risk."

Of the whole question of maternal mortality I can think of no single phase which invites the attention of the profession with greater promise of profit than this broad question of morbidity and all that it implies. Lord Playfair wisely said on one occasion "The record of deaths only registers, as it were, the wrecks that strew the shore, but it gives no account of the vessels which were tossed on billows of sickness,

TABLE 9—Maternal Deaths at Royal Victoria Maternity Hospital 1906-1934

strained and maimed as they often are by the effect of recurrent storms."

A comprehensive view of this whole question is hindered by the lack of a uniform yardstick with which to measure with any degree of accuracy degrees of morbidity. We have suffered a multitude of counselors, for at the present time there are in operation many standards: (1) the British Medical, (2) the British Board of Health, (3) the American College of Surgeons, (4) the Strasbourg Conference Standard

Chart 4—Morbidity and fetal and maternal mortality from 1906 to 1934 at the Royal Victoria Hospital. A single rise in temperature to 100.6 F (after the first twenty-four hours) classes the case as morbid.

Various hospital units throughout this continent have established their own standards of morbidity. For example, in the Chicago Lying-In Hospital every woman is morbid with a temperature of 100 F or more once at any time that she is in the hospital. In the Royal Victoria Hospital, Montreal, a temperature of 100.6 F at any time post partum exclusive of the first twenty-four hours, constitutes morbidity.

Realizing that many complications are of such a nature as to be overlooked if one relies solely on grades of fever, Ward¹³ of New York suggests a wider classification to include all complications in the antepartum, intrapartum and postpartum periods. This is all true, but for a beginning no one standard of

Chart 5—Temperature chart in the morbid cases. Actual number of cases: public 121, private 65, antepartum and postpartum 18, making a total of 204. Morbidity: public 11.5 per cent, private 10.7 per cent, a total of 11.2 per cent.

measurement could be more accurate than the acceptance throughout this continent of a solitary standard of pyrexia, by the profession, as a measure of morbidity. This would be the most constructive step ever taken in the war against sepsis. The morbidity chart would then truly be to the obstetrician what the bone

TABLE 10—Influence of Age on Mortality

plate has always been to the general surgeon a rigid test of the prevailing technic.

Charts 4 and 5 depict graphically what could be recorded from an institutional point of view in this respect. These charts will quickly answer these very vexing questions:

- 1 The value of any special technic, such as the introduction of antiseptics into the vagina during labor.
- 2 The influence of interference in the course of labor, together with the incidence of morbidity after certain operations.
- 3 The advent of streptococcus carriers.
- 4 The location of the high morbidity centers and therefore of the high mortality centers throughout the country. It would inevitably influence the infantile death rate.

The greatest contribution to obstetrics would be the establishment of a common standard.

The necessity for the antepartum supervision of the primigravida is generally recognized, but the needs of

¹³ Ward G. G. Goff B. H. and Aldridge A. H. Bull. Am. Coll. Surgeons 10:9 11 (March) 1935.

the multipara are not so readily accepted by the public or by the profession. She is looked on as a safe performer and undue supervision is often considered superfluous.

Reports from all hospitals, if carefully scrutinized, will soon disprove this fact.

TABLE 11—Comparative Mortality Risk According to the Number of Children

| Children Born | Average Maternal Risk per 1 000 Births |
|---------------|--|
| 1 | 8.80 |
| 2 | 6.74 |
| 3 | 6.32 |
| 4 | 6.05 |
| 5 | 6.21 |
| 6 | 6.23 |

Leyland Robinson¹⁴ states that the mortality risk for a woman of 40 is three times as great as that for a primigravida of 18. He submits the data in table 11, prepared by Coghlan, and recalls that, obstetrically speaking, old age may approach in a physiologic or pathologic manner, or combined, since few individuals are free from some organic defect or weakness.

Even in the presence of health, tissue changes as a result of physiologic wear and tear reduce the activity of the organs and absorb their reserve power. Such impairment of function will in the course of time reach a point at which the whole reserve power is fully mobilized and the individual is incapable of further effort. Such changes would in particular impose great strain on the excretory system during pregnancy and on the musculature and heart during labor, lowered resistance, incapacity for work, undue sensitiveness to fatigue are the natural sequences.

The action of advancing age on any organic defect or disease is dependent on many factors and especially on the site and nature of the lesion. Many diseases are progressive in character, and their disabling effects increase with age, witness the cardiac and the nephritic.

CONCLUSIONS AND RECOMMENDATIONS

Since puerperal infection still remains directly or indirectly the most conspicuous single cause of death following childbirth, every effort should be expended toward its prevention.

Pathogenic organisms, chiefly of the streptococcus family, must be prevented from reaching the birth canal, irrespective of whether it is from the nose and throat of attendants, the patient herself, her husband, or other patients. Endogenous infection must be cleared up.

The use of masks, properly constructed and applied, must be adopted by all those in close contact with women in labor. No person with respiratory or other infection should be in attendance, and the known carriers of streptococci should be constantly supervised. The day is not far distant when, for these reasons, certain people will not be able to undertake maternity work.

In hospital practice, patients exhibiting any signs of infection must be promptly segregated, and at the time of seasonal infections the utmost care should be exercised in the segregation of all suspects.

The adoption in obstetrics of many of the principles that have been so successfully applied in surgery, for example, the more careful examination of the prospective mother with a view to establishing her ability to

stand the strain of labor will do much toward lowering the mortality rates. Again, more attention must be directed to the mechanical problem in hand, for after all the simple fact remains that, in a normal woman with a normal pregnancy, the presenting part should be in the pelvis in the last month.

The impression is gaining ground that more care is necessary in the education of students and physicians in the supervision of pregnancy, in combating the rising incidence of operative obstetrics such as forceps delivery and cesarean section, and in the building up of a more efficient maternity service.

The provision of antepartum clinics, in itself admirable, cannot in any way be construed as a measure of prevention that will be an infallible guide. It is very necessary that those in charge should have a lively sense of what constitutes a healthy prognosis.

This bespeaks the close correlation of all agencies engaged in this work. Teamwork in obstetrics must prevail.

1390 Sherbrooke Street W

ADRENAL CORTEX EXTRACT

EDWARD C. KENDALL, Ph.D.
ROCHESTER, MINN.

Since the classic work of Addison on adrenal deficiency in patients, the adrenal gland has occupied a position of great importance and fascination. A study of its chemical nature and physiologic function has followed the usual course of studies on the other ductless glands. The first step was the proof that the gland is essential for life. This has been known for many years. The second step was the proof that within the gland some substance or substances are present which can be separated and used in substitution therapy. The work of Hartman¹ and of Swingle and Pfaffner² conclusively established the fact that the life of adrenalectomized rats, cats and dogs can be maintained with an extract of the gland.

About eighteen months ago the separation of a crystalline fraction was reported³ which possessed the essential physiologic activity in dogs and patients. This was given with a diet that contained sodium chloride in amounts slightly higher than normal. Three patients have been maintained with the crystalline material for periods of from fourteen to thirty-six days. When the crystals were withdrawn and the administration of the same amount of salt was continued, definite symptoms of adrenal deficiency developed. These results, and similar experiments on adrenalectomized dogs with the addition of sodium chloride, showed that the typical symptoms which followed removal of the adrenal glands could be controlled by the crystalline fraction separated from protein, epinephrine, phospholipids and all other substances of either an acid or a basic nature.

I shall not at this time report on the chemical nature of the crystalline material other than to say that it is a

hydroxy aldehyde which apparently contains twenty-one atoms of carbon and is consequently of high molecular weight. The first crude separation of crystalline material contains more than one substance. The fractionation of this combination of substances into single entities is a difficult matter. The work is now under intensive investigation and will be reported as rapidly as definite conclusions can be made.

THE FUNCTION OF ADRENAL CORTEX EXTRACT

Since 1930, when evidence for the presence of the cortical hormone was obtained, active investigation of the physiologic effect of the extract has been carried out in many laboratories. These results may be summarized by the statement of four theories. Hartman⁴ has suggested the function in general terms that the hormone is an essential cellular agent which is used throughout all the tissues. Britton⁵ has suggested that the function of the adrenal cortex is involved principally in carbohydrate metabolism. Swingle, Pfiffner and others⁶ have suggested that all the symptoms of adrenal deficiency are produced by a decrease in the volume of the blood and that the function of the cortical hormone is to maintain a normal blood volume. Loeb⁷ and Harrop⁸ and their co-workers have suggested that the cortical hormone is involved in the metabolism of sodium chloride.

STANDARDIZATION OF ADRENAL CORTEX EXTRACT

Three methods for the standardization of adrenal cortex extract have been developed. The first method is based on the survival of adrenalectomized animals, or on the growth of young adrenalectomized rats.⁹ The second is based on a determination of the amount of extract necessary to maintain the animal in a normal condition in regard to weight and activity and to hold the blood urea at a level not more than 100 per cent greater than that at the beginning of the experiment.¹⁰ The third method is based on the capacity to perform work. This is measured usually with the rat, either by means of a revolving cage or by direct electric stimulation of a muscle.¹¹

PHYSIOLOGIC ACTIVITY OF ADRENAL CORTEX EXTRACT

Hartman has suggested "cortin"¹² as the name for the extract of the adrenal cortex. It has now been

shown¹³ that adrenal cortex extract can be prepared which will maintain dogs and patients in a normal condition provided the diet contains a slightly increased amount of sodium chloride. Without sodium chloride patients with Addison's disease and adrenalectomized dogs slowly develop weakness and symptoms of adrenal deficiency. In dogs, the urea may be greater than 100 mg in each 100 cc of blood. Administration of large amounts of this preparation of adrenal cortex extract does not reduce the blood urea. However, the administration of sodium chloride with the adrenal cortex extract will promptly restore the blood urea to normal. Sodium chloride alone, in the amounts used with the extract, will not maintain either patients or dogs in a normal condition. For clarity and brevity I shall call such a preparation of adrenal cortex extract A.

A preparation of adrenal cortex may be made from the adrenal gland which is active in the absence of added salt. If a sufficient amount of this preparation is given, the blood urea is reduced to a normal value and the adrenalectomized dog appears to be normal in every respect. Such a preparation may be designated B. When these two preparations are standardized by muscle stimulation it is found that preparation A, with salt, will permit the animal to react in a normal manner. Preparation B, however, may possess but slight activity when measured by this criterion. The most active preparation of adrenal cortex extract is one that combines the physiologic responses of both A and B. At the present time it is impossible to state that the physiologic responses of A and B are caused by the presence of two separate and distinctly different substances. This, however, is suggested by the results. The demonstration that the maximal physiologic response is produced only by the combination of the two solutions, which possess different physiologic activity, obviously complicates the use of a physiologic criterion. This fact, however, may explain some of the discrepancies that have been observed by workers in various laboratories when attempts were made to evaluate the physiologic activity of different preparations of adrenal cortex extract. It has been shown that the action of solution A is concerned principally with the capacity for muscular activity. In its presence, muscles can respond to prolonged stimulation. Solution B has little effect on the muscles, but its action is strikingly demonstrated by its effect on the blood urea and on the retention of sodium chloride.

The retention of sodium chloride by the normal animal organism over long periods, even on a diet that contains a minimal amount of sodium chloride, has been demonstrated.¹⁴ Loeb⁷ and Harrop⁸ have both shown that one of the most striking abnormalities in an animal which has been adrenalectomized is loss of control of sodium metabolism. Sodium chloride is rapidly excreted, and, in order to maintain a normal level of sodium chloride in the blood, it is necessary to give between 5 and 6 Gm of sodium chloride a day to a dog whose body weight is from 15 to 20 Kg.

The investigations of Marine and Baumann,¹⁵ Loeb⁷ and Harrop⁸ and their co-workers have emphasized the intimate relation between the adrenal gland and

mineral metabolism, and the work of Rogoff and Stewart,¹⁶ Zwemer¹⁷ and others has shown that Ringer's solution or sodium chloride will increase the period that animals survive after adrenalectomy. Some significant results have recently been obtained which still more strongly indicate the great importance of normal mineral metabolism. Mr. Allers¹⁸ has shown that life could not be maintained in two adrenalectomized dogs with sodium chloride alone. There was loss of weight, loss of strength, and, although the sodium chloride and urea contents of the blood were within normal limits, there was a progressive decline in the bicarbonate and sugar of the blood. Administration of sodium bicarbonate, or of a sodium salt of an organic acid such as sodium citrate, brought about a rise in the alkali reserve to normal and coincidentally a rise in the blood sugar to normal. With a balanced diet that contained about 6 Gm of sodium chloride, 5 Gm of sodium citrate and a small amount of potassium, two dogs have been maintained, one for eighty-four days and one for 115 days. The dogs both increased in weight, one by 25 per cent and the other by 10 per cent. These dogs were thoroughly studied before the present diet was given. It was shown that typical symptoms of adrenal deficiency developed, as did abnormal values for urea, chloride, bicarbonate and sugar in the blood, unless adrenal cortex extract or the diet outlined was given. When the experiment was started, one dog had a blood urea of 175 and the other of 55 mg per hundred cubic centimeters. The survival periods of these two dogs set a new record. Mere survival, however, does not seem to be the most significant result. These dogs were in an excellent condition throughout the many weeks during which adrenal cortex extract was not given. By proper diet the sodium chloride, alkali reserve, urea, blood sugar and blood volume may be maintained within normal limits. This observation indicates that adrenal cortex extract is not directly concerned with the metabolism of carbohydrates, protein or fats, since a normal condition can be maintained in the absence of adrenal cortex extract, provided a diet satisfactory with regard to its mineral constituents is used.

RELATION BETWEEN ADRENAL CORTEX EXTRACT AND THYROXINE

A relation between adrenal cortex extract and thyroxine has been demonstrated by Koelsche.¹⁹ He has shown that animals maintained on a minimal daily dose of adrenal cortex extract will develop acute adrenal deficiency if thyroxine is given. Animals that are maintained on an adequate amount of adrenal cortex extract will withstand injection of thyroxine without the usual general systemic reaction and without significant loss of nitrogen. If an insufficient amount of adrenal cortex extract is given, thyroxine produces a systemic reaction that is marked in both intensity and duration. These results indicate a close relation between adrenal cortex extract and thyroxine. Whether adrenal cortex extract will be of value in the treatment of acute hyperthyroidism has not been shown clinically.

It is well known that injections of large amounts of the active constituents of the ductless glands produce symptoms typical of hyperactivity of the respective glands. Experimental hyperthyroidism, hyperparathyroidism, hyperinsulinism, and the toxic effect of theelin are well known. It is interesting that the administration of large amounts of adrenal cortex extract will not produce symptoms that simulate the clinical syndrome seen in cases of hypertrophy of the adrenal cortex. Since the most profound disturbance in the animal organism caused by removal of the adrenal glands is associated with mineral metabolism, failure to produce toxic effects by the administration of large amounts of adrenal cortex extract is in keeping with the view that adrenal cortex extract is concerned with the mineral metabolism rather than with the intermediary metabolism of carbohydrates, fats and proteins. Present knowledge of the chemical nature of adrenal cortex extract also suggests that the syndrome seen in tumors of the adrenal cortex may be due to dysfunction and the production of an abnormal substance rather than to an excessive production of the normal constituents of the cortex.

CLINICAL RESULTS WITH ADRENAL CORTEX EXTRACT

By the use of preparations of adrenal cortex extract possessing the physiologic activity that has been described, a large number of patients with Addison's disease have been treated at the Mayo Clinic, and during the past two years no patient has died under our direct observation from adrenal deficiency alone. In three cases, however, the survival of the patient has resulted in the development and extension of tuberculosis in various parts of the body, in one caseiliary tuberculosis developed, in another there was an exacerbation of pulmonary tuberculosis, and in the third tuberculosis of the spine developed with abscess formation. The first two patients died with tuberculosis as the principal cause of death, and, as Snell²⁰ has pointed out, it seems highly probable that patients with Addison's disease which is adequately controlled with adrenal cortex extract may develop tuberculous lesions in other parts of the body, and this adds greatly to the difficulties of treatment. Two patients with severe Addison's disease which was controlled with adrenal cortex extract have undergone major operations—one nephrectomy and the other a spinal bone graft. Three patients have been operated on for tumors of the adrenal glands, definite symptoms of adrenal deficiency were present after the operation, and the patients probably would not have survived without adequate treatment with adrenal cortex extract. These results are evidence that surgical operations, even in the presence of Addison's disease, are now possible.

Before the isolation of insulin, surgical operations on the diabetic patient were attended with a high mortality. Experience has shown that surgical intervention in Addison's disease has a far greater risk than in diabetes.²¹ Even the type and duration of the anesthesia are of great importance. By the use of a satisfactory preparation of adrenal cortex extract, which is now available, the surgeon can operate without undue risk on patients with Addison's disease, and operations on tumors of the adrenal gland itself may dramatically,

bring about restoration to a normal condition²² For the group of patients under our observation, adrenal cortex extract has proved to be as specific and useful in Addison's disease as is insulin in diabetes²³

ARTIFICIAL PNEUMOTHORAX IN THE TREATMENT OF LOBAR PNEUMONIA

FRANCIS G BLAKE, MD
MARION E HOWARD, MD
AND
WINIFRED S HULL, MD
NEW HAVEN, CONN

The present paper is based on the treatment of forty-two cases of lobar pneumonia with artificial pneumothorax between December 1933 and April 1935. Special emphasis will be laid on (1) the method of treatment evolved during the course of the study, and (2) an attempted definition, still tentative, of the conditions under which artificial pneumothorax would appear to be therapeutically useful.

LITERATURE

Artificial pneumothorax was apparently first used in the treatment of pneumonia during the influenza pandemic of 1918-1919 at Takoma Park, D. C., by Rood,¹ who was sufficiently impressed with the results obtained in the treatment of three cases to write "The use of this operation as a therapeutic measure in selected cases is worthy of further trial." A little later Friedemann² in Berlin and Wynn³ in Birmingham, England, used the procedure in the treatment of lobar pneumonia. During the ensuing decade only three papers⁴ on the use of artificial pneumothorax in lobar pneumonia appeared, although the method was tried⁵ during this period in prolonged and complicated cases of broncho pneumonia in infants and children. In 1932, however, following Coghlan's⁶ stimulating report on the treatment of six cases of acute lobar pneumonia, a widespread study⁷ began, the results in 124 cases of acute

pneumonia having been recorded down to the present time. Of the 124 cases, ninety-three have been subjected to analysis.⁸

In general the procedure followed has been that used by Friedemann.² Thus, thirty-four of the ninety-three patients received only one treatment, usually in the neighborhood of from 300 to 500 cc., forty-six received only two treatments usually given from eighteen to forty-eight hours apart, while only eleven received a third and only two a fourth. Furthermore, only nine patients were given a total of more than 1,000 cc. of air, the maximum amount given being 1,650 cc. in each of two cases. From these data it would seem that insufficient air was introduced to cause more than a moderate collapse or retraction of the involved lobe in the great majority of the cases. As will appear later, the method of treatment which has been evolved during the course of our study differs considerably from that generally used.

The four most frequent clinical effects reported are prompt relief of pleural pain, relief of dyspnea, diminution, often striking, in the general toxic phenomena of the disease, and a critical fall in temperature shortly after the induction of artificial pneumothorax, sometimes permanent, though often only temporary. Clear evidence is lacking, however, that pneumothorax treatment serves to cure the disease, since in the majority

Fig 1—Effect of artificial pneumothorax on the course of lobar pneumonia in ninety three cases recorded in the literature.

of the recorded cases in which treatment was not started until the fourth day of the disease or later, approximately one half failed to exhibit any apparent modification of the natural course and outcome of the disease, and prompt critical recovery without relapse appears to have occurred in only one of nine cases treated on the second day of the disease and in only three of fifteen treated on the third (fig 1).

SELECTION OF CASES

In the selection of cases for treatment it seemed to us of importance to direct our efforts primarily to a study of the effect of artificial pneumothorax on the early stages of pneumonia. Consequently all patients with unilateral pneumonia admitted to the medical service of the New Haven Hospital not later than the third calendar day of the disease during the period covered by this report have been treated without selection, twenty-four in number. The remaining eighteen patients in whom treatment was begun on the fourth or fifth day of the disease,⁹ were arbitrarily selected.

Summarized data concerning the cases are presented in the tables.

⁹ In this analysis six cases of bronchopneumonia, three cases in which the day of the disease was unknown, and the twenty-two cases previously reported by ourselves¹ have been omitted.

⁹ Treatment was attempted in three additional cases but extensive pleural adhesions prevented the introduction of air into the pleural cavity and they are consequently excluded from the series.

METHOD OF TREATMENT

The technic employed has been that commonly used immediately following the preliminary examination of the patient an x-ray film¹⁰ of the chest is taken to confirm the clinical diagnosis and to make certain that the pneumonia is unilateral. Following a preliminary dose of morphine, artificial pneumothorax treatment is started. Treatments are ordinarily given with the patient in the lateral position with the pneumonic side

are taken after every 50 to 100 cc of air has been introduced, the treatment being continued until the desired intrapleural pressure is attained. If (for any reason) it is found necessary to have the patient in the prone or sitting position during the treatment, the mean pressure should ordinarily be raised to about 4 cm higher than the desired level in the lateral position, since the pressure will fall approximately 4 cm whenever the patient changes from the prone to the

hours apart and followed, if necessary, by a third treatment eighteen hours later, might be sufficient to accomplish the desired result. This procedure was found to

Fig 3 (A M)—Illustrating temporary improvement with relapse under inadequate treatment

establish a mantle pneumothorax without selective collapse of the involved lobe and to raise the mean intrapleural pressure to -3 to -0.5 cm. It appeared to be satisfactory in the first two cases treated, one of which is illustrated by A C (fig 2, table 3). By the

time nine cases had been treated, however, it had become apparent that this procedure was inadequate, since, following temporary clinical improvement, relapse was found to occur as the intrapleural pressure fell (A M, fig 3, table 2), provided antibodies had not appeared in the blood, as was subsequently found to have happened in the first two cases.

In view of these results the procedure was changed, as illustrated by V G (fig 4, table 2). From three to five initial treatments were given at intervals of approximately four hours in order to establish a mean intrapleural pressure in the neighborhood of $+1$ cm. to $+2$ cm and to induce a complete collapse of the whole lung on the involved side, provided adhesions did not interfere. The first three treatments were ordinarily of 500 to 800 cc each. Subsequent treatments were given at irregular intervals in an effort to maintain a positive intrapleural pressure and complete collapse of the lung until permanent recovery seemed assured or further treatment inadvisable. Gradually a further modification was tried, in which the initial treat

Fig 4 (V G)—Illustrating change in procedure to frequent small initial treatments serving to raise mean intrapleural pressure to positive level. Transient elevation of temperature on seventh day coincident with falling intrapleural pressure

ment was increased in amount and the early refills were given at somewhat less frequent intervals. At the same time, with the purpose of avoiding temporary increase in dyspnea, the rate of introduction of air was cut down from an average rate of approximately 30 to 40 cc per minute, which had been previously used, to an average rate of 10 to 15 cc per minute. At this slow rate, large amounts of air can apparently be administered without difficulty. This procedure, as used in recent cases, is illustrated in R A, figure 5, table 1.

The volume of air required to raise the mean intrapleural pressure to $+1$ cm to $+2$ cm has been found to vary greatly from case to case and cannot at present be correlated with any measurable factors, nor can it be predicted. Ordinarily it will range from 1,800 to 2,400 cc. The time required for the large initial treatment consequently will vary. If 1,800 cc is given and it is administered at an average rate of 12 cc per minute, the treatment will take two and one-half hours to complete. The rate of fall in intrapleural pressure

restlessness, dyspnea and toxemia, has been well described by others¹² and our experience is in harmony with theirs, this subject will not be elaborated here and attention will be directed toward the effect of pneumo-

Review of the forty-two cases treated suggests that the most important factor influencing the results, apart

over the uninvolved left upper lobe prevented collapse of this lobe. All four patients recovered promptly without further extension of the pneumonia and without complications, except for a transient acute psychosis in W L, a patient suffering from severe chronic alcoholism. The course of events in R A, shown in figure 5, and in J S, shown in figure 6, serves to illustrate the results obtained in early cases.

GROUP B Treatment Begun Between Twenty-Four and Forty-Eight Hours After Onset—Data concerning the nine cases in this group are shown in table 2. In the first six cases without adhesions all but A M (fig 3), who was treated early in the series, received initial pressure adequate to raise the mean intrapleural pressure to atmospheric level or above and to collapse the whole lung on the involved side. All showed prompt clinical improvement with relief of distressing symptoms. Recovery was rapid in H K and apparently accelerated in all but R F, who nevertheless was much improved.

COMMENT
The observations on the use of artificial pneumothorax in the treatment of forty-two cases of lobar pneumonia that have been presented appear to indicate

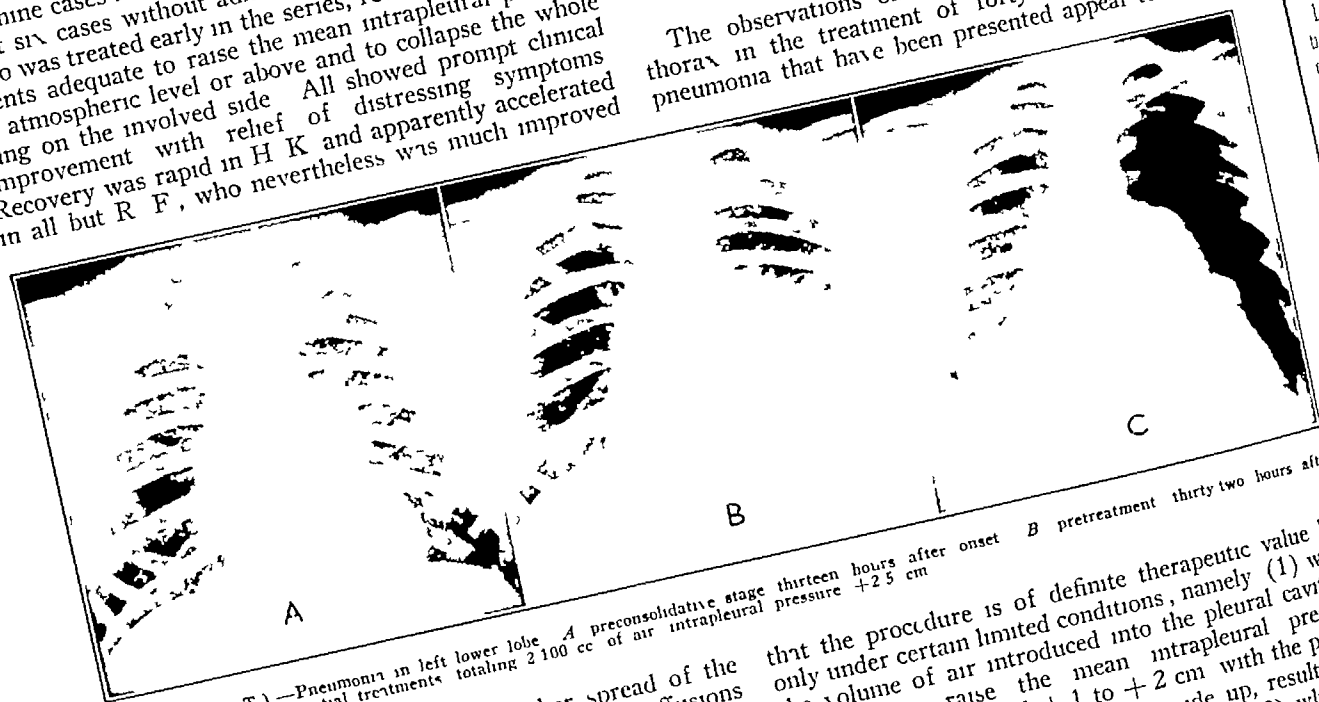

Fig 8 (D T)—Pneumonia in left lower lobe. A preconsolidative stage thirteen hours after onset. C after three initial treatments totaling 2100 cc of air intrapleural pressure +2.5 cm.

symptomatically. None showed further spread of pneumonia. In two cases sterile pleural effusions developed that were sufficiently large to warrant withdrawal by aspiration. No notable effect on the symptoms or course of the disease resulted in the three cases in which pleural adhesions were present, presumably because the adhesions interfered with adequate collapse of the involved lung. Three patients in group B (F H, E E and T G) showed a transient bacteremia following the institution of pneumothorax therapy apparently without ill effect. The course of events in D T¹³ without adhesions is shown in figures 7 and 8 as illustrative of the results obtained in this group. Presumably a more prompt recovery would have ensued if treatment had been instituted on the first day of the disease in the preconsolidative stage (fig 8 A).

GROUP C Treatment Begun Between Forty-Eight and Seventy-Two Hours After Onset—The fifteen cases in this group are summarized in table 3. Of the six patients without pleural adhesions four recovered promptly by crisis, G S¹⁴ with spread to the opposite side but relapsed, G S¹⁴ with spread to the opposite side, A C (fig 2) R D and J F, however, showed antibodies in the blood on the fifth, third and sixth days, respectively, so that early recovery may have been the

that the procedure is of definite therapeutic value but only under certain limited conditions, namely (1) when the volume of air introduced into the pleural cavity is sufficient to raise the mean intrapleural pressure promptly to a level of +1 to +2 cm with the patient in the lateral position, pneumonic side up, resulting in complete retraction of the affected lung, (2) when the

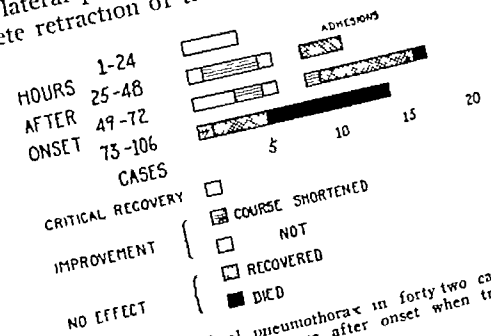

Fig 9—Effect of artificial pneumothorax in forty-two cases of lobar pneumonia grouped according to time after onset when treatment was started.

frequency of refills is sufficient to maintain the mean pressure at this level and the lung is retracted until the danger of relapse is past, (3) when treatment is instituted early in the disease, i e, certainly within less than seventy-two hours after onset, probably within less than forty-eight hours in most cases, (4) when the pleura is free from adhesions that interfere with retraction.

tion of the involved lung. The signal importance of the time factor is clearly shown in figure 10, which summarizes the results in the forty-two cases treated.

Experimental observations bearing on the mechanism by which artificial pneumothorax exerts its apparent effects have been presented elsewhere¹⁵ and will not be discussed in detail here. In brief, they show (1) that respiratory motion of the involved lung can be abolished by artificial pneumothorax, provided the amount of air introduced is sufficient to cause maximum retraction of the lung on the treated side, (2) that antibody production is not demonstrably accelerated by pneumothorax therapy, and (3) that there is little evidence to support the view that relief of a hypothetical bronchial occlusion takes place following pneumothorax treatment. Consequently the theory that the effects of artificial pneumothorax depend on immobilization of the infected lung would appear to be the most acceptable one at present.

CONCLUSIONS

1 Artificial pneumothorax, when administered so as to induce and maintain complete collapse of the lung or the involved side, would appear to be a useful therapeutic procedure in the treatment of lobar pneumonia but only when used early in the disease, preferably within twenty-four hours after onset.

2 There is no evidence to support the view that it is of curative value later than seventy-two hours after onset.

3 Further trial of artificial pneumothorax in lobar pneumonia is desirable and should be carried out before any statistical analysis of results obtained is warranted.

ABSTRACT OF DISCUSSION

DR. ALFRED STENGFL, Philadelphia. When Friedman's and later the more convincing paper of Coagland appeared it was hard for some physicians to believe that this disease could be so treated safely and effectively. One thing established by them and by those who have followed, was that pneumothorax properly performed may be done in cases of lobar pneumonia with safety. That circumstance may have led to some of the erroneous conceptions to which the earlier papers led. The results that were obtained for example in Coagland's work were entirely too good to be believed and it seems probable that some of the earlier results obtained in cases of pneumonia advanced beyond the first day or two probably represented spontaneous recoveries of persons who were not unfavorably influenced by the pneumothorax but who would have recovered without it. Unless this treatment is used very early in the disease the chances of its doing definite good are not brilliant. On the other hand I cannot believe that there is not something fundamental and radical that pneumothorax does in a case of early pneumonia. The authors put aside the thought that there is any speeding up of formation of antibodies by pneumothorax and the explanation must be sought elsewhere. I believe that the way in which this subject must be pursued in the future for the elucidation of these points is by animal experimentation. Much may be added by the trial and error method in further clinical studies but to obtain a real solution of the mechanism that operates here, a well thought out and rather extended series of investigations bearing on many factors that might conceivably enter into the subject will be required. This treatment is not yet on a basis that should permit the medical profession to assume that, because certain people have obtained occasionally brilliant results this is a treatment to be performed by those who know little more about the details of it than that pneumothorax has been done and that the patients have recovered. The selection of cases the training in the giving of pneumothorax and a great many other factors enter into it. I think that it would be rather unfortunate if this should be accepted now as being an established treatment for

pneumonia to be practiced broadcast or widespread. Much more work must be done before it can be accepted as a routine.

DR. JESSE G. M. BULLOWA, New York. Since the publication of Coagland's paper I have applied pneumothorax in the treatment of pneumonia forty-two times in thirty-one cases before the seventy-second hour. The extent of pneumothorax was controlled by repeated roentgenograms. In my experience I have encountered little from which to infer that pneumothorax treatment of pneumonia, even when applied on the first day of the illness, has beneficially influenced the progress of the disease and some things that lead me to believe that the reduction of the aeration area may be definitely detrimental and add the disadvantages of anoxemia to the toxemia and the possible bacteremia. I have seen an extension of the lesion in the lobe that was involved, and an extension of the lesion to another lobe on the side under collapse, happen in a patient suffering from pneumonia due to pneumococcus type VIII treated on the third day. The lower lobe was involved and collapsed. The temperature came down slightly and on the sixth day though collapsed the left upper lobe became involved and the temperature rose. The contralateral side became involved in three cases as exemplified by a patient suffering from pneumonia due to pneumococcus type V, in whom the pneumothorax was induced at the nineteenth hour for involvement of the left lower lobe. Good collapse occurred but there was no favorable influence on the temperature and pulse from the repeated introduction of large amounts of air. The heart became displaced to the right. On the second day the blood culture became positive. Extension to the right lower lobe was found in a roentgenogram taken at the thirty-fifth hour. The patient then had to have air removed from the left side because of respiratory distress. He became delirious. On the fourth day type V antiserum was begun and he was placed in the oxygen chamber. He required a million units. Had he been treated with serum on the first or second day he would have required only several hundred thousand units. He recovered. In five cases the blood has been invaded during treatment. There has not been dramatic relief of pain in every case. There has been more frequent delirium than usual in the pneumococcus type I pneumonias. The problem of pneumonia is the bacteremia. If there is no bacteremia, it is amazing how much a patient will stand and yet recover. In reference to the eighteen patients with type I pneumonia, six of whom died with bacteremia, I have had 239 cases due to pneumococcus type I treated on the fourth and fifth day with specific serum but without pneumothorax. Thirty-three patients died 139 per cent. This treatment is not a treatment for general practitioners or for those who have little experience with pneumonia or few facilities for treatment. Of 100 cases of seven different types of pneumococcal pneumonia, in which no specific treatment was given, some terminated on the first or second day. Many cases of type I terminated on the fifth, sixth or seventh day. Most of the cases terminated between the fourth and twelfth day. The curve for each type was somewhat different. Until the appearance of such a chart is changed by a treatment for pneumonia, that treatment cannot be said to be beneficial.

DR. FRANCIS G. BLAKE, New Haven, Conn. We have made a considerable number of studies on patients concerning the mechanism involved. We have found no evidence of any accelerated production of antibodies nor evidence in support of the view advanced by Holmes and Randolph that the induction of pneumothorax induces crisis by expelling exudate from occluded bronchi. We have been able to demonstrate by fluoroscopic study in a considerable number of patients that there is complete immobilization of the inflamed lung so far as respiratory movement is concerned. It is our opinion that this is probably the mechanism by which artificial pneumothorax exerts its effects. Our eighteen cases of type I pneumonia six of which were fatal were late cases or there were adhesions and type I serum also was given in three cases. In our experience, as already stated the treatment of pneumonia, after the third day with artificial pneumothorax accomplished nothing in the way of cure. I agree with Dr. Stengel that it is too soon to use the method widely because all the conditions under which it is or is not beneficial are not yet known.

AN ANALYSIS OF LIVING PATIENTS
WITH PRIMARY MALIGNANT
BONE TUMORSWILLIS C CAMPBELL, MD
MEMPHIS, TENN

The object in this discussion is to analyze 100 cases of malignant bone tumor in which apparent cures have been effected, fourteen of which are from my private records. Eighty-six are from the Sarcoma Registry of the American College of Surgeons, of which eighty-five are accepted five-year cures, seventy-four are osteogenic sarcoma, ten are Ewing's sarcoma, and one is myeloma. One is a doubtful case of osteogenic

Classification of Primary Bone Tumors

sarcoma and is not accepted. Of 125 patients with primary malignant bone tumors from my private records there are thirty living and well at the present time but only the fourteen cases in which sufficient time has elapsed to determine probable results and in which I am reasonably certain of the diagnosis will be considered.

Primary malignant tumors are classified for study as (1) osteogenic those derived from any of the elements which are factors in the formation of bone, and (2) nonosteogenic, from tissue residing in bone but in no measure connected with the formation of bone, as marrow cells, endothelium of lymph and blood vessels, and connective tissue. The classification of primary bone tumors is best illustrated by the accompanying table.

Of the fourteen cases under discussion there were ten osteogenic and four nonosteogenic sarcomas. The number of patients with osteogenic sarcomas of the different types who are living and well may be enumerated as follows: osteolytic sarcoma in children, none, osteolytic sarcoma in adults, three, primary chondromyxosarcoma, two, secondary chondromyxosarcoma, two, chondroblastic sarcoma, two, chondrosarcoma, one, and osteoblastic osteogenic sarcoma, none.

In no case of the typical osteolytic osteogenic sarcoma in the young did the patient live more than two years from the time of onset. This tumor is evidently a clinical entity, the most primitive type being composed largely of embryonic cells, and is quite a different tumor from the medullary tumor of adults, often designated as osteolytic. Of nine adult patients with osteolytic osteogenic sarcoma there are three living and well, twelve, twelve and four years later. It is doubtful whether this type in adults should be placed at this point in the chronological order of evolution, as some

of the cases show a much higher tissue development than osteolytic osteogenic sarcoma of children.

CASE 1—H L, a white man, aged 22, had had pain and tumefaction over the lower extremity of the left tibia for four months. Roentgenograms showed a distinctive medullary process, which had in places destroyed the cortex with apparently no reactive changes in the bone. At biopsy the bony shell of the cortex was found to be very thin and in areas destroyed. Within the cortex was a distinct cavity, which was partially filled with apparent grayish yellow granulation tissue that completely covered the osseous surface. A block was taken and frozen sections were made which revealed a malignant tumor, fibrosarcoma, this was later confirmed by a permanent section. The patient is now living and well more than twelve years later. The leg was amputated at the junction of the upper and middle thirds.

CASE 2—A Negro woman, aged 39, noticed a knot on the left leg just below the knee four years before admission. One year previously she fell about 2 feet and thinks she broke her leg as she could not walk for several months. When the patient was examined, she walked with crutches. There was a tumefaction of the knee and soft tissue of the upper extremity of the left tibia, the growth extending anteriorly and laterally about 3 inches above the surrounding surface of the skin. Roentgenograms demonstrated cystic changes of the upper extremity of the left tibia resembling a giant cell tumor which had broken through the cortex. May 16, 1923 an incision was made over the tumor, the upper extremity of the tibia was exposed and the cortex broken through. Within the bone was a very soft pale gray tumor containing no bony material. The cortex was broken through on the lateral and posterior surface with the tumor protruding. All tumor tissue was curetted out of the bone and the wound closed without drainage. A microscopic examination was made by several pathologists who made the diagnosis of "round cell sarcoma," definitely malignant. Such a term is now obsolete, but as there was every evidence of a malignant condition, such as mitotic figures and disorderly arrangement the limb was amputated above the knee, May 24. Recovery was uneventful and the patient is living and well more than twelve years later.

From the roentgenogram I thought that the tumor was probably a giant cell tumor or osteoclastoma and

Fig 1—Osteolytic type of osteogenic sarcoma occurring in a young person which in the author's experience is fatal in 100 per cent.

treated it accordingly, amputation was not done until pathologists agreed as to its malignant condition. In this case there is some doubt as to whether this was not originally a giant cell tumor, though there were no giant cells present. There may also be some question as to malignancy, but it is my opinion that the tumor was malignant though not to a high degree.

CASE 3—E C, a man aged 30, admitted May 21, 1931, for one year had noticed pain and disability in the left knee which had gradually increased with some loss in muscle control. Recently the pain had become more severe. On examination there was tenderness of the external condyle of the left femur and in the popliteal space with some fullness. Extension was possible to 160 degrees and flexion to 80 degrees. Roentgenograms showed multilocular cysts in the outer condyle and in the lower end of the shaft. The cortex expanded and was broken through posteriorly. May 22 an

incision was made for biopsy over the lateral surface of the leg beginning at the condyle and extending upward for a distance of about 7 inches. The bone was chiseled through and the tumor mass was found occupying both condyles and about 6 inches of the shaft. The posterior portion of the external condyle was destroyed and the tumor was invading the popliteal space for a short distance. As there was considerable doubt as to malignancy, the entire tumor was removed from the interior

Fig 2—Embryonic type of osteolytic sarcoma occurring usually in the young but occasionally in adults. Note large tumor giant cells.

of the bone and was composed microscopically of semisolid bluish pink, semitranslucent glistening elastic tissue. As the microscopic examination indicated a malignant condition, amputation at the junction of the upper and middle thirds of the thigh was carried out, May 24. Convalescence was uneventful and the patient is now living and well after four years.

Two cases were osteogenic sarcoma (cases 4 and 5) in which the diagnosis was primary chondromyxosarcoma, being composed of a preponderance of cartilage and myxomatous tissue, both patients are living and well, eight and one-half and six years later, respectively.

CASE 4—T R E, a man, aged 51, admitted Nov 1, 1925 had injured the left ankle two and one-half years previously, followed by moderate pain and swelling. For one year there had been increased swelling and a rapidly growing tumor. Overlying the external malleolus of the right ankle there was a tumor mass $3\frac{1}{2}$ by $3\frac{3}{4}$ inches slightly ovoid, the overlying skin slightly blue, and rubbery in consistency, the tumor was not painful to pressure and was apparently continuous with the bone. Movements of the ankle were normal. November 2 a biopsy was done, a diagnosis of malignant tumor was made from frozen sections. Amputation was performed. The laboratory of the Baptist Hospital reported a typical chondromyxosarcoma. The patient had an uneventful recovery and has been living and well for a period of eight and one-half years.

CASE 5—L H, aged 19 years, was admitted Jan 3 1929. April 28 1928 there was onset of pain in the upper third of the right tibia with gradual swelling and increase in pain. There was a history of trauma one month prior to onset. The patient had been operated on three times. There was continuous drainage of serosanguineous fluid. Examination showed a fungous, cauliflower like growth of about 5 by $2\frac{1}{2}$ inches projecting from 1 inch to 3 inches above the skin surface of the upper third of the anterior aspect of the tibia secondarily infected, and bleeding easily. The patient was very anemic with hemoglobin of 44 per cent. Biopsy was performed January 5, a frozen section revealed chondromyxosarcoma. Amputation was done at the same time. The tumor was of short duration—nine months—but had been operated on three times without metastasis, which has been noted in a number of cases in which cures have been effected by amputation. The patient is living and well after a period of six years.

The Sarcoma Registry confirmed the diagnosis, eight of ten experts agreeing that the tumor was a very malignant osteogenic sarcoma of the same character as diagnosed.

Six patients had osteogenic sarcomas that were apparently secondary to a preexisting lesion in the bone of whom two are living and well.

CASE 6—Miss B S, aged 28 admitted Dec. 8, 1927, complained of pain and swelling in the right knee, which she had noticed one year before. The swelling gradually increased, pain became very severe and was present day and night. Weight was maintained and the appetite was good. The patient walked with the knee flexed. Apparently attached to the lower third of the femur was a hard round mass about the size of a baseball to which the skin was not attached. There was pain on pressure, motion was limited to from 100 to 160 degrees by pain. Roentgenograms showed a circumscribed osseous tumor with destructive changes in the center. December 9 a longitudinal incision was made over the medial aspect and a tumor was exposed, which was apparently surrounding the shaft of the femur. A frozen section did not settle the question of malignancy. The wound was closed. A later report confirmed the malignant condition and amputation was carried out at the junction of the upper and middle thirds of the thigh. The final diagnosis was osteogenic sarcoma (chondromyxosarcoma). From the roentgenogram it was very suggestive that the new growth developed on a former benign osteoma, but from the history it was equally indicative that the tumor was primary and if an osteoma was present, the patient was unaware of it.

CASE 7—Mrs C R C aged 38, admitted Sept 14, 1930, complained of pain in the lower left jaw that had been present since March 1930. After a few weeks a small enlargement appeared on the back portion of the lower jaw. All teeth had been extracted two years previously. Roentgen treatment had been given for two months. Examination showed a rounded enlargement about three-fourths inch in diameter, of the descending ramus of the left lower mandible slightly tender, with no palpable glands. October 2 an incision was made over

Fig 3—Osteogenic sarcoma in youth aged 19 of nine months duration. Apparent cure by amputation.

the alveolar process. The tumor consisted of fibrous, bony tissue and cartilage arising from the outer table and medulla of the mandible. The entire tumor, outer table and medullary contents were excised for about 2 inches. The tumor did not appear malignant. It recurred in two months with a fungating mass. This was excised with about 4 inches of bone. March 25, 1931, there was a third recurrence at which time the entire right jaw including the condyle was removed on the right and on the left to the ascending portion leaving the joint on the left side intact. There has been no recurrence. The diagnosis was osteogenic sarcoma of the chondromyxosarcoma type.

MALIGNANT BONE TUMORS—CAMPBELL

1498

The pathologist and the Sarcoma Registry with one dissenting voice agreed to the diagnosis of osteogenic sarcoma. I believe, however, that the tumor was secondary to a low grade inflammatory process, as there was some condensation of bone which did not resemble a

Of our series of osteogenic sarcoma, there are three cases in which the diagnosis was chondroblastic osteogenic sarcoma, a type of tumor that apparently arises from the epiphysis during adolescence, but to me it is somewhat doubtful whether it is materially different from more common types, such as chondromyxosarcoma and osteoblastic sarcoma

CASE 8—B H, aged 16 years, admitted Dec. 5, 1931, had had a slight injury several months previously by bumping the leg with a block of wood. Three months before, pain had begun in the left knee on weight bearing. An enlargement was noticed, which had gradually increased, and the pain had become more severe. The patient walked with a limp in the left leg. A firm tumor involving the upper end of the tibia, which was materially increased in size, was very painful on deep pressure. There was full range of motion in the knee. The inguinal glands were not enlarged. There was increased local temperature. Roentgenograms showed condensation, mottling and destruction, with erosion of the cortex and radiating striae of bone into soft tissue, very suggestive of osteogenic sarcoma. The lungs were normal. December 7, biopsy resulted in the report of osteogenic sarcoma, very malignant. Amputation was done above the left knee. Coley's toxin was efficiently

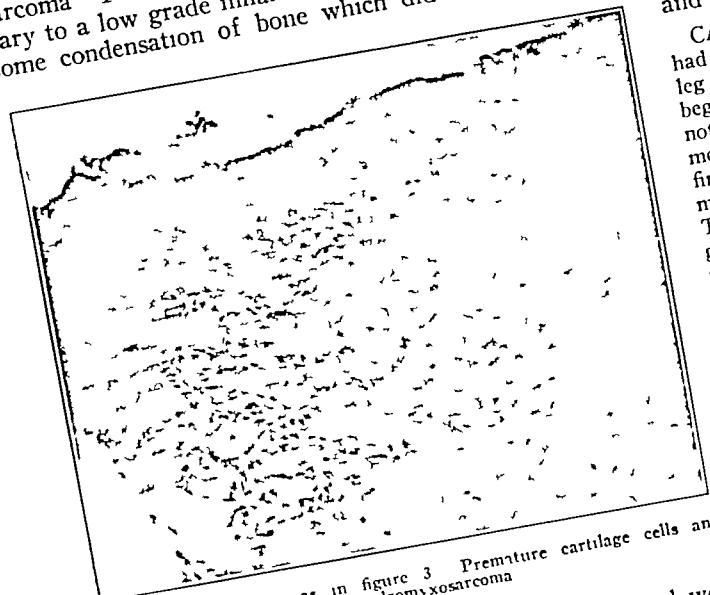

Fig 4—Same case as in figure 3. Premature cartilage cells and myxomatous tissues typical chondromyxosarcoma

sarcoma in this region. The patient is living and well over a period of three years, which is some indication of a successful result but not sufficient to be regarded as a cure. The case is interesting in that there were a number of recurrences and a number of operations

Fig 6—Growth resembling typical fibrosarcoma but in other sections showing few cartilage cells and myxomatous tissue

administered for a period of two years with uneventful recovery. The patient is living and well four and one-half years after the operation.

This case was observed early with a history of only three months' duration, however, the process was probably present with symptoms for some time before medical aid was sought. A diagnosis might probably have been made at a much earlier date if the patient had presented himself.

CASE 9—H E B, a man aged 22, admitted May 12, 1932, had noticed a small tender mass over the upper portion of the right tibia three months previously. This became painful and increased in size. When examined by an intern at the Baptist Hospital in Memphis, Tenn. one month previously, the roent genograms made were negative. The patient was dismissed to return in one month. During the past month the mass had become larger and more painful. Examination revealed a firm nodular mass on the lateral surface of the upper extremity of the right tibia which was not very tender, and gave no local heat. On admission the roentgenogram showed condensation suggestive of a malignant condition. May 16, at operation, incision revealed a firm, nodular tumor about 1 inch in diameter arising from the tibia. The portion removed for biopsy was found to be malignant. Section of the tumor was firm and grayish and had the consistency of cartilage. Gross and

Fig 5—Secondary osteogenic sarcoma in a patient aged 28 living five years

which have been noted in those in which cures have been effected. This group is of especial interest, as the tumors apparently arise in secondary osseous lesions, which may be removed and thus the tumor prevented. This is similar to the prophylaxis of carcinoma.

microscopic pathologic changes were similar to those in case 8. Amputation was done at the middle of the thigh. The permanent section was diagnosed by all experts of the registry as osteogenic sarcoma. Our pathologist regarded the tumor of the chondroblastic type of osteogenic sarcoma, and two experts of the registry as chondrosarcoma. Other members of the registry confirmed the diagnosis osteogenic sarcoma. The patient returned to our clinic Feb 16 1933, showing definite recurrence in the stump as indicated by a large nodular mass which surrounded the amputated end of the femur. Disarticulation was done at the hip the pathologic nature of the tumor being the same as the original. There has been no recurrence and the patient is living and well three years later.

This case, just as case 8, was observed comparatively early but radical treatment should have been instituted one month earlier when first observed by the intern. The metastasis in the stump might not have occurred if efficient treatment had been carried out at that time. This is another case in which there has been recurrence with a certain arrest over a longer time than usual and a possible cure.

Fig 7—Very early osteogenic sarcoma of chondroblastic type amputated in midthigh patient living and well after three years. Early amputation in such cases gives relatively excellent prognosis. A April 13 1912 B May 14 1932

CASE 10—B C G a man age 38 admitted Aug 11, 1919, had been struck on the left leg by a buggy wheel in a runaway, May 12, 1918. At first he was able to walk one block, then he was in bed for one or two weeks and on crutches for four weeks. The diagnosis made by Dr Johns of Stuttgart, Ark. was fracture of the fibula which was confirmed by a roentgenogram. After two weeks only occasional pain was felt until the following spring when he noticed enlargement of the outer aspect of the left leg just below the knee and pain became more severe and radiated to the interior aspect of the leg. Examination revealed an irregular hard mass on the upper third of the left fibula about 3 inches in diameter. A roentgenogram demonstrated a transparent mass in the soft tissues and erosion of the upper extremity of the fibula. An encapsulated mass with the upper third of the fibula was excised. It was composed of large lobes, apparently hyaline cartilage. Microscopic examination showed that the tumor was composed of hyaline cartilage. The diagnosis was chondroma. March 10 1920 the tumor had recurred and was of the same character but much more extensive, about three times the former size. The entire tumor was again resected with much difficulty. October 27 the tumor had again recurred and the limb was amputated at the junction of the middle and lower thirds of the thigh. As the tumor showed some myxomatous degeneration and grew so rapidly with recurrence twice after apparent excision the tumor has been classified as a chondrosarcoma.

since hyaline cartilage predominated. The tumor may also be regarded as a chondromyxosarcoma.

This type of tumor, especially in a man of his age, is not very malignant and possibly in the early stage the tumor was a benign chondroma in which there was a

Fig 8—Same case as in figure 7. Recurrence of tumor of amputated stump of femur which required disarticulation at hip joint.

secondary stage. The registry classifies the tumor as an osteogenic sarcoma.

Of the periosteal fibrosarcoma group, three are dead and one is living.

Fig 9—Same case as in figures 7 and 8.

CASE 11—Mrs G L S admitted May 27 1932 had a recurrent tumor of the heel since the age of 4 with four or five recurrences and operations for excision the last operation being performed in 1929. On examination the operative scar on the inner side of the left ankle below the internal malleolus showed soft tissue swelling extending from the scar down under the os calcis back to the achilles tendon and forward to the region of the scaphoid. Nodular enlargements were present

in the tumor mass, with the superficial veins dilated, and were tender to pressure. Motion was limited in dorsiflexion and eversion. Roentgenograms demonstrated apparent invasion of the os calcis on the inferior aspect. There were no signs of malignant tumor of the bone. On admission, biopsy demonstrated malignant fibrosarcoma of the large spindle type, which was confirmed by a permanent section. June 3 amputation was

extremity of the right tibia with marked destruction in the region of the internal malleolus. There was some new bone production and swelling of the soft parts and marked osteoporosis of the bones of the foot. February 18 a frozen section was indicative of a malignant condition. Amputation was done at the junction of the upper and middle thirds of the leg. Coley's toxin was given for four months. There has been no evidence of recurrence and the patient is living and well eight years after amputation. All experts of the registry agree as to the diagnosis of Ewing's tumor.

This patient was much older than those in which this tumor usually occurs.

CASE 13—E. L., aged 12 years, admitted May 20, 1931, had pain in the ankle two years before and noticed tumor one year before. November 1930 an incision was made for an abscess and again in 1931. The wound had not healed and there was a discharging area. There was a large soft tumor mass at the lower end of the left tibia with draining ulcerated areas. There was severe pain on attempted motion of the ankle. Roentgenograms revealed extensive destruction with expansion of the lower fourth of the shaft of the left tibia with marked lipping at the junction of the shaft with the tumor. May 21 a diagnosis of malignant tumor was made from a frozen section. Amputation was done at the lower third of the left thigh, followed by irradiation and Coley's toxin for a period of six months, after which the patient was advised to use Coley's toxin at home but carried it out in a desultory manner.

An uneventful recovery followed, with no recurrence to the present time (the patient is living and well after four years). This tumor had also been operated on on two previous occasions, evidently with a diagnosis of osteomyelitis, which is a common error in Ewing's tumor. There is much difference of opinion among the members of the registry, five in favor of Ewing's tumor and three in favor of osteogenic sarcoma. Our pathologist believes the tumor to be Ewing's tumor. Irradiation in all probability would have resulted in differentiation, as all Ewing's tumors respond favorably to some extent, but it was thought that the safest procedure was to amputate at once. The registry classifies this as Ewing's tumor.

CASE 14—J. O. T., a man, aged 21, admitted Aug 3, 1930, had been operated on elsewhere April 13, 1930, for acute osteomyelitis of the right tibia, and holes were drilled in the bone with relief. In the latter part of May there was a recurrence with afternoon temperature of about 99 F. One week before admission pain was more excessive and the temperature reached 100. The leg became swollen and very tender and the local temperature increased. Examination of the right leg showed a healed scar about the middle third. There was tenderness to moderate pressure over the middle third of the shaft, and thickening of the bone with increased local temperature. Roentgenograms revealed condensation and slight enlargement of the middle third of the tibia with evidence of three drill holes from the former operation. August 4, operation was carried out with decompression of the tibia over the middle third, a portion of the bone about 4 inches in length and about three-fourths inch in width being removed, material resembling pus was present in the medullary cavity, which was curetted, local detritus being gently removed and sent to the laboratory.

Fig 10—Chondrosarcoma. Note that the tumor is well encapsulated. Not included in report of cases as patient declined treatment.

done through the junction of the upper and middle thirds of the leg.

This tumor is comparatively rare, as there were only four in our series of 125 primary malignant bone tumors. The prognosis of this tumor is said to be better than any other type of malignant bone tumor and is practically the same as fascial sarcoma of the extremity with the same prognosis.

Of twenty-one patients with endothelial myeloma (Ewing's tumor), three are living and well eight, five and four years later, respectively.

Fig 11—Osteogenic sarcoma chondrosarcoma type approaching adult hyaline cartilage.

CASE 12—A. L. M., a man, admitted Feb 17, 1927, complained of pain in the right ankle one year before. A tumor appeared about Dec 1, 1926, and had grown rapidly since, with no fever or intermittent attacks. He walked with crutches. The tumor of the ankle, most marked on the anterior medial aspect, was 'rubbery' on palpation, not definitely encapsulated and apparently connected with the tibia. There was slight local heat. Motion was limited about 25 per cent in all directions. Roentgenograms showed a tumor of the lower

Fig 12—Typical osteoblastic osteogenic sarcoma occurring in a boy aged 12 years, which was fatal within a few months. Recovery has not occurred in any of our cases of this type.

for examination. A petrolatum gauze pack was put on the wound. The diagnosis was osteomyelitis. Culture was negative. August 26 a permanent tissue report gave a diagnosis of definite malignant tumor, osteogenic sarcoma. The patient was advised to return for further study. September 8 the patient returned with more pain and marked tumefaction. Roentgenograms demonstrated excessive bone production and tumefaction of the soft parts. The wound was discharging serosanguineous fluid but no pus. A malignant growth was suspected. A second biopsy was made which grossly did not appear malignant, and more tissue was taken for further study. Amputation was deferred. In the meantime roentgen treatment and Coley's toxin were instituted and have been rigidly and efficiently maintained for a period of eighteen months. The tumor rapidly receded, the wound healed and the bone returned to about normal with the exception of some permanent condensation.

The report of the registry is most interesting. Five observers make a diagnosis of Ewing's tumor, one of malignant tumor, probably Ewing's, and one simply of sarcoma, and one does not believe the tumor to be malignant. When one takes into consideration the evidence of the experts, combined with the fact that the tumor responded so rapidly to radiation, the diagnosis is very suggestive of Ewing's tumor.

Of the fourteen cases there are ten registered and one pending registration, and three were seen before we were registering every case as a routine.

The statement has been made that those who are cured by amputation or excision often give a history of several previous operations prior to final radical treatment. Of these fourteen cases, seven gave a history of

amputation was at or above the joint proximal to the tumor which suggests that all amputations should be proximal to the affected bone.

The fact that many of the successfully treated patients had undergone previous and often extensive local operations is an argument in favor of biopsy.

Fig. 14.—Same patient as in figure 13. Masses of polyhedral cells and scant intracellular substances; few mitotic figures.

Fig. 13.—Ewing's tumor in lower extremity of tibia, an unusual site. Note lifting which is characteristic also of osteogenic sarcoma. Patient is living and well after four years.

Ewing regards biopsy as a dangerous procedure that materially increases the chances of metastasis.

The prognosis is better in adults as the age advances, though of less frequent occurrence. Seven patients were above 30. Seven were below 30.

From the history, age and clinical symptoms there were five cases that we regarded as highly malignant and we are fortunate that these patients are still living. They are patients 5, 8, 9, 13 and 14. Nine cases on account of adult age, history and other indications should give a high percentage of recoveries. In nine cases from five to fifteen years has elapsed without recurrence, in five cases from three to four years, these are included in the report, for if two years elapses after apparent cure with no evidence of metastasis the chances are that the five year period will be reached.

There are no cases of osteoblastic or osteolytic tumors in children to report, as all nineteen cases of osteoblastic and nine cases of osteolytic have ended fatally, except two recent cases. These types we have found to be more common in children, with practically 100 per cent mortality. Also, Ewing's tumor is of frequent occurrence in childhood, but the prognosis is not as poor. The pathologic reports and an analysis of the five year cures of the Bone Sarcoma Registry are omitted for the sake of brevity.

The problem of bone tumors is analogous to cancer but by far more difficult, as malignant tumors of bone are less frequent but much more malignant. The results at present, as is well known, are far from desirable, but there has apparently been some improvement during the past decade from the impetus given to the study of the subject by the Sarcoma Registry, though there are no previous or reliable data for comparison. However, a concentrated effort by members of the profession, especially those of this section, who treat a majority of the bone lesions of this country, could probably do much to improve the present status of primary malignant bone tumors.

869 Madison Avenue

previous operations. Of sixty-three patients who died, six had a history of previous operations. However, a large percentage presented themselves for treatment in the latest stages after extensive destruction. In five cases the point of amputation was above the tumor through the same bone, and in seven the point of

ABSTRACT OF DISCUSSION

DR. HENRY W. MEYERDING, Rochester, Minn. The fact that Dr. Campbell's cases were all carefully followed up, that he had the roentgenograms and the microscopic sections passed on by himself, his pathologist, and then, in most instances, verified by the Registry of Bone Sarcoma, puts this paper above the average presented on the subject of sarcoma of the long bone. I believe that he states correctly that it is only through earlier diagnosis that more satisfactory results from treatment are going to be obtained. I have advocated for years biopsy at least in all suggestive bone lesions. The value of a biopsy depends on its interpretation by the pathologist, and it is well known that one cannot always depend on pathologic opinion. Furthermore, before attempting surgery, one should roentgenograph the chest for pulmonary metastasis. I favor biopsy and do it in every suspected bone lesion. A diagnosis of a malignant state is no longer sufficient. The pathologists grade the degree of the malignant condition, and at times that proves of value in deciding the possible point of amputation. Many patients come to the clinic with apparently small tumors, of either the osteogenic or Ewing type, and the routine examination shows evidence of pulmonary metastasis. It is believed that further knowledge along the line of radiosensitivity of the cells and improved technic in irradiation will be of value in the future. However, at present, roentgen and radium treatment have not been very encouraging, although in the case of Ewing's tumor a therapeutic test by irradiation is almost as conclusive and satisfactory as a pathologic opinion. Dr. Campbell has shown a case of malignant transformation of an apparently benign lesion that later proved to be malignant. I have seen that happen when all the data possible were at hand—x-ray, history, serologic test and pathologic opinion, all of which were negative only later to find that the true nature of the tumor was brought out by evidence of metastasis to the lungs. In a series of Ewing's tumors recently gone over, I find that a high proportion had been previously diagnosed as osteomyelitis. In every case of osteomyelitis in which suspicion of Ewing's tumor arises, I would be in favor of a therapeutic test by irradiation. I believe that the classification as shown by Dr. Campbell the registry classification, has done much to simplify and to permit a more readily understood differentiation of bone tumors.

DR. BRADLEY L. COLEY, New York. Dr. Campbell is to be congratulated for setting the example of registering his cases and referring to them by their registry diagnosis. The ultimate accomplishments of the Bone Sarcoma Registry are hard to predict. I agree with Dr. Campbell that the most valuable place for the use of toxins is in the treatment of endothelial myeloma. I would emphasize the fact that, until some dramatic discovery changes our entire conception of the bone sarcoma problem, improved results must be looked for in the education of the public and the profession, so that these conditions are suspected, investigated roentgenographically, their presence proved or disproved and proper treatment instituted at the earliest possible moment. When the profession accepts and follows the dictum that persistent pain in an extremity or in any part of the skeletal system calls for the tentative diagnosis of bone sarcoma until such is disproved, physicians will begin to see these cases at a period when treatment may offer a more hopeful prognosis, and the end results will be improved. At present I believe that the following statements are justified: 1. Ewing's sarcoma is both radiosensitive and toxin sensitive and irradiation should be used for the local lesion and toxin for its systemic effect and especially to prevent generalization of the disease. Irradiation by high voltage roentgen therapy with the single dose technic, is then followed by intensive toxin treatment. Irradiation alone has produced few, if any five year survivals. Radical surgery is therefore probably indicated for accessible lesions after radiation therapy has produced the maximal regression. This period may roughly be taken as from four to six weeks. 2. Osteogenic sarcoma is best treated by early amputation. At the present time results of irradiation do not justify its being offered as first choice. However, for osteogenic sarcoma in young children there is more reason to substitute it for immediate amputation, since the latter almost never produces a cure. Toxin therapy has been of value after amputation for osteogenic sarcoma in preventing the development of pulmonary metastases. I use it as a routine after all

amputations. 3. The results of irradiation alone have been distinctly inferior to those of radical surgery for operable osteogenic sarcoma. However, in my experience, irradiation has often produced marked palliation, and I invariably give it a trial in all cases when the lesion is inoperable or when radical surgery is refused. Further efforts should be made to develop a method of irradiating these patients that will offer a more favorable outlook. May I point out the opportunity that is open to orthopedic surgeons, who are most apt to see the sarcoma cases, to play a leading part in the fight to control this disease. Dr. Campbell stands almost alone among orthopedic surgeons as a careful student, an experienced clinician and a valued contributor to this field, which seems to me so definitely to belong in the realm of orthopedics.

DR. WILLIS C. CAMPBELL, Memphis, Tenn. There is sufficient evidence to warrant the use of Coley toxins combined with radiation in Ewing's tumor, but in osteogenic sarcoma without amputation in these cases there was no beneficial result. Possibly there may be some value in the toxins after amputation, but it is difficult to carry out unless the patient can be under clinical supervision for a year after amputation. One patient is living four years after amputation and Coley toxins have been efficiently administered for eighteen months while another patient is living and well after three years without toxins. I am employing the toxins after amputation in osteogenic sarcoma when possible, but the value can be determined only by the results in a large series of cases after amputation with and without this treatment. No one man can accumulate a sufficient number, and it is only by cooperative efforts by such groups as members of this section that conclusions can be reached. The mortality is so high in the more malignant types that a thorough test of this or any other method should be made. Dr. Coley and others have produced sufficient evidence to warrant a scientific investigation of this treatment in a large number of cases.

STEREOSCOPIC FUNDUS PHOTOGRAPHY

CHAIRMAN'S ADDRESS

ARTHUR J. BEDELL, M.D.

ALBANY, N. Y.

The highway of health is lined with memorials erected to those who have advanced the art and science of medicine. Every discovery in medicine and surgery is commemorated, some by large imposing structures, others by small tablets, but to the historian every one recalls important facts, so that this avenue is life's most famous road. To the multitude certain mementoes appeal, while the specialist is particularly interested in those most closely associated with his division of the healing art.

Ophthalmologists gaze with wonder and admiration at the pyramids built in memory of great anatomists, pathologists, physicians and mathematicians but stand spellbound before the cenotaph raised in recognition of the many who conceived and developed the ophthalmoscope, with grateful hearts they approach the cluster of marble shafts memorializing the originators of the slit lamp and then pass down the thoroughfare to a few broken, moss-covered pillars placed in remembrance of the photographers of the fundus. Symbols of attempts that ended in disappointments, they have acted as inspirations to those who in the heat of the midday sun looked with awe on them, took new courage and finally achieved success.

In the quiet of the evening we think of the men who have labored and who are now working in this part-

Read before the Section on Ophthalmology at the Eighty Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1935.

Because of lack of space this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reprints.

ticular field. We look about and find collected near the great monuments many stones that make an impressive mound constructed as a tribute to the pioneers who were filled with a natural longing to preserve the appearance of fundus changes.

There is a piece for Roseburgh, who in 1864 attempted to photograph the fundus of an animal, here a block for Noyes and another for Liebreich, they failed, but their failures led others to greater effort. To one side a marble slab for a former chairman of this section the beloved scientist Lucien Howe, who described his unsuccessful efforts in 1887, while a short distance farther along there is a relic for Bagnieres of France recording his work in 1889, and a bright rock signifies that Gerhoff in 1891 succeeded in taking a fairly good photograph.

We pass many year miles where the rubble and talus indicate long periods of investigations, unsatisfactory results and heart-breaking frustrations before we reach the polished granite column elevated in recognition of Dimmer of Vienna who in 1899 electrified the ninth International Congress of Ophthalmology with his marvelous pictures. His cumbersome apparatus was expensive and its manipulation so technical that only one was built but his photographs were not duplicated for several years.

To Salomonsen, whose excellent camera is used by several there is a special tablet, and in this isolated section we find the notations of Wolff, Thorner and others who aided in bringing us all nearer the realization of our dreams.

Nordenson brought some clear photographs to the Washington congress in 1922.

With the exception of Dimmer, almost all the investigators associated with our present methods are living. They are scattered over the world from Nordenson in Sweden to Pavia in Argentina, from Wessely in Germany to Guist in Vienna and in America from Von Der Heydt in Chicago to scores in other cities. The work is steadily growing in importance and in value, for a host of clinical ophthalmologists are preserving their observations for posterity to examine and appraise.

Three atlases of photographs have appeared, the first by Dimmer and Pillat in 1927, my own in 1928 and Guist's in 1934. The same year a monograph was published by Nordenson. The literature is far too voluminous even to summarize.

Direct color photography has attracted attention and some excellent pictures have been presented, but because of the expense and the difficulty of reproduction it is as yet not popular. Eventually, drawings will be supplanted and even the most skilful artist forced to admit the superiority of photographs. For several years I have been taking colored photographs.

Fig. 1—Choroideremia and high myopia. 1 Right eye choroideremia. 2 Left eye choroideremia. 3 Macular region of left eye choroideremia. 4 Compound myopic astigmatism dark macular region.

Pavia and Baillart, working independently, have made moving pictures of the fundus, which so far have proved to be surprising but not especially enlightening.

The obelisk from which an effulgent light is radiated and the Mecca toward which all disciples of permanent accurate records make their pilgrimage is that reared in 1926 to Nordenson for his photographing ophthalmoscope, and it is here along this beaten track that we

linger and in solitude examine the archives of photography of the fundus

Stereoscopic fundus photographs were first mentioned in the literature by Metzger in 1927. Some of mine, taken from a collection which was started Oct 2, 1926, were submitted for publication on March 15, 1927. There are three methods of taking these photo-

ment is limited, for a satisfactory negative cannot be secured unless the pupil is at least 7 mm in diameter and, for the finer detail, 8 mm. It is impossible with this camera to take pictures of the cardiovascular-renal group in which the pupil cannot be fully dilated.

If one refers to some of the rare ophthalmoscopic appearances that have been presented at recent sessions of this section, one can readily appreciate the value of stereoscopic fundus photographs in choroideremia and angioid streaks.

CHOROIDEREMIA

C. W. F., a man, aged 45, with choroideremia, was first examined and photographed on March 15, 1934. He had worn glasses fifteen years the last pair for four years. He thought that he had perfect vision until about one year before examination, at which time he noticed dancing bubbles before both eyes and shortly thereafter found it impossible to get around after sunset. Until that time he had been active in sports, including baseball. He had typhoid when he was a child, scarlet fever in early adult life, an operation for mastoiditis and also one on the right kidney. He presented no evidence of venereal infections and the Wassermann reaction was negative.

The right eye (1, fig 1) was normal externally. Vision was 18/200. The pupil measured 4 mm and was regular and reacted normally to light and in accommodation. The pale disk was slightly oval with a thick uneven nasal margin and a shallow central excavation. The retinal vessels divided and passed as an upper and lower branch, these again subdivided and continued without unusual course or caliber changes. Several fine vessels extended over the disk, but there were no chorioretinal ones. Both arteries and veins were about half their normal size, but neither system showed irregularity of the lumen or unusual distribution. The choroid was almost entirely absent, although careful examination with red and blue light disclosed faint remnants in isolated regions, as about the disk, where a delicate pattern suggested the choroidal vessels and a thin uneven coat of retinal pigment. The latter varied from a dense, dark reddish brown irregular area between the disk and the macula to a weblike barely visible shading. Surrounding the macula the pigmentation was somewhat triangular and almost twice as long as the disk in its greatest diameter.

The darkest portion was the pyriform or flattened oval of the macula itself, which was sharply differentiated in the photograph but not so clearly distinguished when seen with the ophthalmoscope. In the periphery of the fundus were scattered flecks of pigment. The white sclera dominated the picture.

The left eye (2 and 3, fig 1) externally was normal and the vision was 6/200. The fundus was almost snow white, the sclera was visible throughout with the exception of a few scattered pigment areas the disk, and the macula. The dull

Fig 3—Angioid streaks 1 Right eye, superior nasal quadrant 2 Left eye upper nasal sector
3 Left eye disk and macula 4 Left eye inferior nasal quadrant

graphs one by the use of the Wessely apparatus, in which the camera remains fixed and the patient's eye is moved, another, the method I introduced, in which the position of the camera is changed and the eye remains fixed on an object held by an assistant, and the third, the absolute, by which the two pictures are taken at the same time by the Nordenson stereoscopic camera. Unfortunately, the range of usefulness of the instru-

gray disk was slightly oval and on the temporal side faded into a faintly pigmented zone while the nasal edge was clearly separated from the retinal pigment which was about one-third the disk diameter in width. The brownish pigment that partly encircled the disk was thin, in places absent and two dark flecks lay beneath the retinal vessels in proximity to it. The vessels divided after passing through the central excavation into a superior and inferior branch and from these major subdivisions large and small ones extended over and beyond the disk. The arteries and the veins were measurably smaller than those in the right eye. The dark macula was almost round, about one third of the disk in diameter and surrounded by a triangular zone of what appeared to be pigmentation but which was in reality the remaining part of the normal retina. The edge of the region was not distinct. All the blood vessels to the macula came directly from the retinal supply, there were no chorioretinal ones.

The field of vision in each eye was very small, ranging from 2 to 5 degrees from fixation.

ANGIOID STREAKS

Angioid streaks of the ocular fundus are neither common nor understood, although 106 cases seem to have been reported in the literature.

C. S., seen Dec 22, 1930, had vision in the right eye (1, fig 3) of 20/15. The total refractive error was $+50 \times 90^\circ$. The pupil measured 3 mm and was regular and active. The media were clear. There were definite brownish pigmented granular streaks surrounding and radiating from the disk. They were all beneath the retina. The upper nasal sector showed the pathognomonic discolored streak extending to the peripheral mottled area.

The patient has been examined at various times since then and the last photographs were made on Nov 3 1934. At the time of the first visit and at subsequent examinations, no changes were found anywhere in the skin of the body.

The detailed examination of the left eye (2, 3 and 4, fig 3) showed that there was an oval disk as measured on the photograph 6.25 mm \times 9 mm. All measurements were so made and must not be considered as ophthalmologic approximations but as true comparatives. The disk surface was slightly uneven and there was no central excavation. The veins and arteries were comparatively straight and all passed over dark, cellular-like brownish channels. These so-called streaks were beneath the retina, either in the deep choroid or between the choroid and the sclera. They were without the regularity of vascular channels resembling neither the straighter retinal vessels nor the more tortuous ones of the choroid. The channels were broadest near the disk. In places as for instance on the temporal side they were close to the edge of that structure whereas to the nasal side they were separated by a band which was almost 2 mm wide. The superior temporal projection extended obliquely up and out for 15 mm and although it

seemed to taper from the center to the periphery it was of unequal width showed a variable pale surrounding stripe and merged into a wider area of similar appearance, devoid of any form even remotely suggesting a blood channel.

Almost directly above the disk there was another streak, which was about 15 mm long. This streak was attenuated and ended in a fainter but otherwise identical zone. To the superior nasal side one of the widest streaks extended about

Fig 4—Allergic fundus reactions. 1 Petechial hemorrhages of retina. 2 Absorption. 3 Another shower of blood. 4 Quiescent allergic retinitis.

22 mm gradually narrowing until it also was lost in the peripheral discolored region.

The remaining part of the fundus was somewhat mottled. Dark specks were within two disk diameters of the broad band that surrounded the nerve head. There was a very definite ampuliform dilatation to the inferior nasal side of the disk. The extensions from this were very granular, in places the pigment seemed to be absent and the reduction in the width of the streak was very striking. Scattered about the disk were

several granular spots of the same appearance but in no way connected with the streaks themselves. The macula was uninvolved and the field of vision unchanged.

The streaks do not seem to be blood channels, for there are no canals like them. They are not reduplications or folds because they are not elevated, and simple wrinkling does not explain the granular appearing areas

that as yet neither the cause nor the structural changes have been correctly explained. The correlation of the photographs and the pathologic condition are essential to the solution of the problem.

ALLERGIC REACTIONS

Allergic reactions are so bizarre that some one recently said that they explained many of the common general phenomena attending disease. If so, there are many ocular manifestations that have as yet escaped detection.

C B, a married woman, aged 52 seen Sept 25 1934, complained of poor vision in the left eye, which had been noted for eleven days.

With the exception of a slight overfulness of the veins and a faint irregularity of the lumen of the arteries, the right eye was normal.

Vision in the left eye was 20/30. The pupil measured 3 mm and was regular and active, and the media were clear. The entire retina was edematous and overspread with superficial striate and somewhat deeper, rounded hemorrhages. The veins were distended but not over tortuous and in places partially hidden by the overlying retina. The arteries were irregular in the lumen, some of them very small, others of normal caliber. The macula was a clearly outlined, irregular dark oval surrounded by deep retinal hemorrhages, a shower of petechial hemorrhages (1, fig 4).

December 6 the patient was again seen. The edema of the retina was decidedly less and the arteries were about the same, but the retinal hemorrhages had all disappeared (2 fig 4).

Fifty three days later the patient returned after having had a left lower molar tooth extracted under procaine hydrochloride. Her physician, Dr A C Hagedorn, reported her blood pressure 143 systolic 78 diastolic, blood sugar was 120, urea nitrogen, 14, platelets, 222 000 per cubic millimeter, coagulation time seven and one-half minutes, bleeding time, two minutes. The blood count showed eosinophils of 15 per cent. The fundus was spattered with blood and unless the photographs were analyzed it might readily have been considered the same as on her first examination. A careful inspection showed however, that the striate and rounded hemorrhage were in different places (3 fig 4). Nothing but photographs could record the multiple petechiae and so clearly demonstrate the changes that had taken place in this fundus.

D H, a man, aged 21, was seen April 21, 1930 following an automobile accident, eight days before which resulted in a fracture of the third and fourth lumbar vertebrae. The right eye showed marked subconjunctival and lid ecchymoses. The pupil measured 4 mm and was regular and active. The media were clear, and the nerve head was completely obscured by thick white edematous swellings which looked like irregular balloons of various sizes and prominence. There were several superficial hemorrhages over them. The arteries were normal.

Fig 5—Papilledema 1 Active stage swollen disk with exudate 2 Subsiding less marked 3 Complete recovery 4 Unilateral stationary disk elevation

in the periphery. They give the impression of bands of atrophy over or into which red-brown debris is dispersed. Certainly the actual stereoscopic photographs in this case will, if the patient is kept under observation long enough, help in the final solution of a curious anomaly. Some cases of angiod streaks are coincident with pseudoxanthoma elasticum, others with osteitis deformans and many without any general disease, so

but the veins were at least twice their normal width. There was slightly less change in the left eye.

I suggested that he had an allergic reaction as a result of the tetanus antitoxin that had been administered. This was confirmed a few hours later when a generalized urticarial eruption appeared. There was a rapid decrease in the retinal swellings, but it was not possible to bring him to Albany until June 9, at which time it was found that the disk was almost perfectly round and the veins were fuller than the somewhat narrowed arteries. The disk was pallid. On the temporal side were several areas of grayish yellow, brilliant remnants of the former edema and in the vitreous, overlying the macula, were many fine gray, pin-point dots (4, fig 4).

These two cases are presented to arouse greater interest in the subject of allergy.

PAPILLEDEMA

Papilledema in either the progressive or the retrogressive stage offers an excellent subject for serial stereoscopic photographs, a clinical method little practiced and less appreciated and yet the most valuable of all records.

A. M., a girl, aged 12 years, seen March 17, 1934, in consultation with Dr. E. E. Hinman, had had an acute nasopharyngeal infection and an acute otitis media on the left side with rather extensive mastoid involvement. At the time of examination the temperature was 106.2 F and with the exception of partial paresis of both external rectus muscles, externally the eyes were normal. There was a marked bilateral papilledema.

It was possible, April 7, to bring her for photographs. The disk was about twice its normal size and elevated at its greatest point about 4 diopters (1, fig 5). The central excavation was maintained and the papillomacular bundle was definitely depressed. The arteries were very small in places entirely obscured by the edema. The veins were distended, partially covered by vascular exudate and whitish yellow streaks which were greatest on the sloping sides of the elevation. There were a few minute hemorrhages and many dilated capillaries.

April 24 there was considerable reduction in the swelling of the disk with almost complete disappearance of exudate, and practically all the excessive vascularization had disappeared except at the superior border (2, fig 5). The veins were about two thirds of their normal diameter. In the lower nasal quadrant the course of the major vein remained hidden by the overlying edema. The disk was less swollen, projecting about 2.5 diopters. Almost all the larger arteries could be traced over the disk. The central excavation was maintained and the papillomacular bundle was distinct.

June 1 after cerebral taps by Dr. Gilbert Horrax the vision was restored to 20/15. The disk was seemingly of normal size, one-half as large as when first examined and although the

nasal side remained definitely elevated it was normal in color outline and consistency (3, fig 5). The left eye followed the same course as the right from the day she was first seen until the last examination, a steady decrease in compression signs.

DETACHMENT OF THE RETINA

Ophthalmic literature is replete with studies and reports on the operative results in detachment of the

Fig 6—Detachment of the retina. 1 Myopia normal fundus. 2 Horseshoe-shaped detachment about disk. 3 More extensive separation. 4 Funnel-shaped disk, ridge detachment projection.

retina, and yet I present this spontaneous retinal detachment because of its unique photographic history.

J. S., a boy, aged 10 years, first seen Feb 20, 1924, had compound myopic astigmatism, with normal fundi. Refraction was done again Jan 7, 1927, at which time there was a considerable increase in the myopia, and the vision was brought to 20/20. There was no annoyance until shortly before a visit on Oct 27, 1931, when the distance vision was blurred, he had

a slight frontal headache after close application and a tendency to hold things closer to his face. The distance vision was 3/200 with his old correction 20/100, with a $-6.50 = -2.50 \times 15^\circ 20/40$, left eye 4/200 with a $-6.50 = -3.00 \times 165^\circ 20/30$? At that time a fundus photograph was taken (1 fig 6) simply as a matter of record and not because there was any gross or unusual change. The disk was perfectly round with a clearly outlined scleral ring and an incomplete pigmented

the eye was normal. A large U-shaped rounded elevation surrounded the lower two fifths of the nerve (2, fig 6). The upper arms were widely separated. The blood vessels on the lower part of the nerve head were intimately associated with the roll. The central excavation was overshadowed by a thin gray, somewhat indefinitely outlined membrane. The portion of the disk in the opening of the U was edematous and its contour indistinct. The difference in level between the highest point of the roll and the other portions of the retina was about 3 diopters. The macular area was small surrounded by specks of gray edema. The field of vision was very markedly contracted varying from the 25 degree to the 5 degree point of fixation.

December 24 the elevated pale U-shaped area was not as sharply contrasted with the rest of the edematous retina which in many places, especially above was striated (3, fig 6).

March 17, 1933 the arms of the U were more acute. The superior opening was narrow and in places where the retina had been striated there was a distinct folded, prominent detachment which widened peripherally, was of very uneven surface and in places showed broad white bands. The contrast between the elevated circumpapillary ridge and the rest of the retina was less distinct so that the blood vessels, particularly those which were formerly in the upper half of the disk, were partly concealed in a deep hole, which was not the central excavation of the nerve head but a depression in the folds of the detached retina. Practically the entire upper half of the retina was detached. The surface was very uneven with many white streaks some straight others curved and all of unequal width. The vessels were adherent to the angulated retinal surface. There were many radiating wrinkles about the macula (4 fig 6).

Externally the eye was normal. September 11. The upper portion of the former U-shaped roll was almost closed by a very prominent, unevenly surfaced, localized detachment of the retina (1, fig 7). The ridge about the disk was pale the depression was marked and the effect on the retinal vessels was still more striking. The impression was that the vessels were fixed and that the retina was bulging forward so as to change their relationship to the region of the nerve. It is quite important to understand that the disk itself had not been visible since the first stage of this widespread retinal detachment. The upper two fifths of the retina showed a series of broad white bands with white

central streaks (2, fig 7). These seemed to be acute angulations of the retinal surface for the retinal vessels passed over them and were always kinked as they followed the acute retinal edge. The great difference in the various levels is well depicted in the photographs.

Jan. 26 1935 the vision of the right eye was 1/200 and unimproved by any glass. The field of vision was bizarre, in only a few isolated areas was light perceived. The entire

Fig 7—Detachment of the retina. 1 Prominent fold about and above disk. 2 Sharp angulation of detachment, white retinal streaks. 3 More generalized flatter. 4 Left eye ridgelike white line sloping detachment.

arc limited to the nasal side. Several branches of the arteries came out of a large central excavation. The inferior vein showed four branches the superior two. The subdivisions of both arteries and veins were not noteworthy. The fundus pigment was somewhat granular and the macula was clearly and distinctly outlined.

Thirteen months later Dec 11 1932 the vision of the right eye was reduced to 20/200 with correcting lens. Externally

retina was so greatly detached that although the light colored ring surrounding the region of the disk was still visible, there were no gross undulations in its surface, and the broad white subretinal bands had disappeared (3, fig 7)

On this day, retinal changes were for the first time discovered in the left eye. The vision was reduced to 2/200 and with correcting lens 20/30. The round disk was sharply outlined by a scleral ring and had a small deep central excavation. There were several branches of the rather straight retinal vessels. A line about six disk diameters long extended from the inferior border of the disk obliquely up and to the nasal side. In places this was a thin streak while in other parts particularly toward its termination, it widened and became whiter. There were several small irregular white flecks near the line and to the upper side of it. The line was the sharp angle of that part of the retina which was most detached, and as the retina sloped on each side it gave the impression of a ridge pole on which taut canvas was stretched (4, fig 7). The choroid circulation was clearly seen. The field of vision was markedly and irregularly contracted.

And so, after this hour of quiet meditation, we leave the isolation of the sector devoted to ophthalmoscopy and again pass down the highway of health with higher aims and a greater desire to add to the luster of our particular specialty, by individual effort and greater familiarity with all the discoveries in medicine and in surgery.

344 State Street.

THE PSYCHIATRIC HOSPITAL AS AN INSTITUTE OF LEARNING

C C BURLINGAME, M.D.

Psychiatrist in Chief, the Neuro-Psychiatric Institute of the Hartford
Retreat and Associate in Psychiatry, Columbia University
College of Physicians and Surgeons, New York
AND

CARL PHILLIP WAGNER, M.D.

Senior Psychiatrist, the Neuro-Psychiatric Institute of the Hartford
Retreat and Assistant in Psychiatry, Columbia University
College of Physicians and Surgeons, New York
HARTFORD, CONN.

It has long been evident to those familiar with mental illness that one very great weakness in the system of institutional care of the mentally ill lay in the fact that the patient, already retreating from reality, by reason of his admission to a hospital became even more completely isolated from community life. Because of the simplified environment, the uncomplicated routine and the lack of usual and normal contacts with outside life the patient tended to become even more desocialized.

We may be presumptuous in undertaking to develop a psychiatric hospital as an institute of learning, but we have proceeded on the theory that fundamental progress could best be made by first regarding all psychiatric hospitals as places for education and reeducation of individual patients and that pedagogic methods under medical guidance should eventually dominate these institutions for both the acute and the chronic patients, not primarily to increase the scholastic knowledge of the patient but for the development of personalities and the emotional stabilization through training and rational psychotherapy.

April 1, four years ago, in accordance with this theory, the old Hartford Retreat was started toward the goal of making the institution into an educational center with as normal an environment as possible. On the premise that people were sent to hospitals because

of their inability to adjust themselves to community life the natural therapeutic approach seemed to be the reeducation of the patient, and it followed, of necessity, that to do this it was necessary to surround him gradually with an environment both physical and personal which would more exactly approximate the normal environment of a normal person.

Naturally, the accomplishment of such an ideal concept has been replete with difficulties. The physical plant had to be adapted to the purpose of an educational institution, the body of employees, professional and nonprofessional, had to be trained to accept the theory and to equip itself for carrying it out. Hence it became necessary to rebuild the physical plant and to create an entirely different attitude in the personnel through a long continued, consistent program of staff education.

One cannot emphasize too strongly the important part that the personnel plays in such a scheme, every one knows that personal associations in environment have a great deal to do with shaping personality, and our objective was, therefore, to select employees for their education, intelligence and capacity to offer something to the patient both in the way of actual instruction and more subtly, but just as really, by a pattern of intelligent normality. In passing, we might say that attendants have been supplanted by psychiatric aides who, according to our requirements, must be at least high school graduates and capable of grasping the psychological factors in the didactic and clinical training concentrated in the aides' six months' period of orientation. This training program extends through the entire rank and file of the organization.

We mention these things as a necessary prelude to an explanation of the things actually being done, so that the philosophy behind it all will be understood, with no philosophy as a basis, the entire structure is meaningless, but, with the educational concept, the objective of which is the development of latent capabilities, the chiseling off of rough and unsocial character defects, the development of a feeling of responsibility, the nurturing of the competitive spirit, and in short the evolution of a normal, healthy attitude toward life, then all these things take on a new meaning. They have meaning because they are in accord with the best educational principles and because we use as a part of our method an approximation of normal community conditions.

It will be noted in a survey of the curriculum that we have dispensed with many forms of so-called occupational therapy which have been identified with institutions for years. Perhaps we have bent backward in an avoidance of anything smacking of institutionalism, but we have not missed these, and we have supplanted them by things more nearly like what these people may expect in the community.

A curriculum is offered which will make for a well rounded and well balanced personality and which provides training along the lines of vocation, avocation, cultural pursuits, physical recreation and social interest.

While we are thus providing educational facilities for the patient at the hospital, we particularly try to project the goal and purpose of these pursuits beyond that period and to stimulate enough interest in these activities so that he will follow many of them through life in much the same way as many of us continue certain cultural, intellectual and vocational pursuits after school or college.

We try to develop good habits of industry by planning a daily program which requires regular hours of

study Courses are provided that will help the individual become more efficient in his vocation or that start his training and interest in a new vocation suitable to his personality These courses are supplied by some of the leading universities of the country under the supervision of an educational director at the hospital Extension courses in business, economics, finance, insurance and government are offered in which the patient is responsible for his work directly to the university Classes in shorthand and typewriting are provided at the hospital As the patient's condition improves and his work becomes more advanced, he is sent to one of the local business schools, where he may get additional instruction along the lines of bookkeeping, accounting, secretarial work and other subjects related to business Under this procedure, it will be noted, the sharp line of demarcation between institution and community life is gradually wiped out

We offer classes in horticulture, including botany, the study of plants and plant life, and landscape gardening, in these courses the patient is provided with regular classroom work In the greenhouse he is given a chance to carry out his ideas in the designing and developing of landscapes in miniature and to learn the practical fundamentals of gardening

Classes in costume designing and the knitting of garments and fashionable accessories, domestic science and interior decorating supply splendid avocational training and frequently serve a very practical purpose as well There are classes in dietetics and party service, in which patients are taught to make dishes that are both attractive and palatable, here again the training is both avocational and practical

From the cultural point of view, patients are instructed in art classes which include sketching, clay modeling, sculpturing and painting Along with these a lecture course in the history and appreciation of art is given by one of the professors of a local university One can readily realize the value that these classes have as a medium of self expression, of creation and of establishing feelings of satisfaction through achievement

Still adhering to the theory of maintaining normal conditions, the library is a very essential adjunct to our educational scheme Through it we provide guided reading in history, music, economics and government in conjunction with classes in these subjects In addition to these reference books, the library contains most of the classics and a good supply of current books on biography, history and fiction Instead of filling our library with books which are old or about which people have stopped talking, we have an arrangement with the publishers to receive advance copies so that our new books may be reviewed in our hospital publication and our patients actually reading them before they can be procured outside This has a good effect, and we find patients taking considerable pride in discussing the newest books with their visitors Superficially a small thing, but one of the small things that prevents the patient from feeling "out of things"

Our physical education courses are offered to supply recreation while the patient is in the hospital to keep him in good physical condition and to create proficiency in sports, so that after developing sustained interest on his return home he is able to meet his friends on a common basis in sports and will be able to engage in competition which will be stimulated by success We offer training in golf, badminton, squash, swimming and other similar physical exercises

Many individuals come to us handicapped by an undeveloped capacity for social activities We devote our evenings to social functions and to amusements such as up-to-date moving pictures, plays, concerts, dances and bridge parties For the person who has been too busy to learn to dance and to play bridge, class instruction is provided so that when he leaves the hospital he is able to enter into the more popular types of social activities with his friends

Here again we must revert to the importance of personnel in putting into actual practice the concept behind the entire scheme We had to train our instructors to think of an individual with personality problems rather than of disease entities such as schizophrenia or manic depressive insanity Shyness, timidity, and ideas of reference can no longer be thought of as symptoms of schizophrenia but must be considered as personality problems based on feelings of inadequacy and fear of frustration With this attitude the therapist no longer feels that he is offering a certain type of occupation which has a beneficial effect on schizophrenia but that he is giving a special type of training which will help the patient to overcome certain personality defects and make a better social adaptation The psychiatrist may help him to understand his attitudes and reactions, but it is the job of the instructors and social directors to give him training in social poise, in cultural pursuits and even in his occupation in order to help dissipate the feeling of inferiority and to overcome his inadequacies

So far we have discussed briefly the various courses But before these courses could be given it was necessary to create the proper surroundings to carry out the educational idea Classrooms were provided in which patients are assembled in small groups In these classrooms an atmosphere of learning predominates and the serious business of study is the accepted type of behavior The patients are scheduled to spend regular hours in classes for study under the direction of an educational supervisor, with practice periods in short hand and typing or in group discussions in some of the subjects previously mentioned

Carrying still further the conception of normal community life, we have built a small street of shops with a beauty parlor and a book shop These are all separated from the main hospital building so that it is necessary for the patient to leave his room and go outside to visit the beauty parlor or the library or to make purchases of cigarets, cosmetics and soft drinks, which are provided at the tuck shops and soda fountain We do not have to point out the significant difference to patients between going out and selecting their own purchases as compared to the usual routine of "dispensing"

In the Modern Made, a little dress shop for women, we display the latest style in lingerie, negligees, lounging pajamas and gowns The dress shop is not used primarily as a salesroom but it does give us the opportunity to introduce costume designing, sewing and knitting, and the garments stimulate interest in our patients Our modiste discourages the purchase of finished gowns and attempts to induce the patient to buy material and make the garment in which she is interested New styles are purchased at the beginning of each season and a fashion show is held which stimulates further interest in the art of knitting and making fashionable accessories such as hats gloves and purses

Needless to say the therapeutic value of this approach is strengthened because of its subtlety, the patient does

not get the impression that we are offering something for the treatment of mental diseases. Throughout we avoid this approach, every one is loath to consider himself as suffering from mental disease, but nearly every one is willing to admit that he is having difficulty in meeting certain problems in life, and it is on the basis of offering training and education to meet these problems that these things are offered to the patient. The educational approach conveys to the patient the idea of remolding certain personality deviations, whereas a general psychiatric approach may imply to the patient a picking up of the broken pieces of a shattered personality and arranging them again.

The atmosphere of learning and endeavor that permeates the entire community and the purposeful, objective attitude of the patient adds impetus and power to the efforts of the physician in trying to gain the cooperation of the patient. Each is striving for a personal objective, and yet it is a common objective, and somehow this community of spirit and of purpose binds all together on a sound basis of cooperation, and the desire for social approval supplies an incentive for the patient to make his personal contribution toward the spirit of the community life.

A schedule of classes throughout the day is given in the tables.¹ A schedule is selected and arranged to meet the needs of each individual patient (table 3). Each of these classes is taught by an instructor qualified in his particular subject, whose chief interest is to develop an aptitude in his special field. These instructors work closely in conjunction with the psychiatrist in charge of a case. Any difficulty that a patient may encounter in mastering the subject, as well as any mental aberration, is discussed with the physician.

After an exhaustive physical and psychiatric examination patients are assigned to a certain group, according to age, mental and physical condition and cultural interests. In this way each patient has an opportunity to associate with others who are congenial and interesting. As soon as possible he is assigned to classes and commences his course of study along lines that have a definite continuity and purpose.

For the patient who is too ill at the time of admission to cooperate in organized classes, instruction is given in his room. With improvement he goes to small classrooms in the various halls where the work, although still simple, becomes a bit more advanced. Gradually as the patient's condition continues to improve he is promoted from class to class until he enters one of the higher groups. On reaching the condition whereby he can circulate from one class to another, he is given a balanced program of organized classes and physical education in which the emphasis is placed on learning and on increasing one's efficiency.

The patient understands that promotion from one class to another depends on the effort and skill with which he is able to perform his assigned tasks. Likewise, the evening social functions are graded, and the patient knows that with improvement he will be allowed to attend functions of the higher social group.

During the patient's interview with the psychiatrist his personality and emotional problems are discussed in detail. Through these therapeutic interviews an attempt is made to reevaluate his emotional bias, and a new approach to his problem is formulated. As a practical adjunct to psychotherapy, the patient is given an

opportunity to try the theoretical solutions gained in therapeutic interviews in the concrete field of reality in this small community. In this way he has the advantage of solving his problem from a theoretical point of view and at the same time is given the added advantage of solving his difficulties through a new approach on a definite training basis.

We do not mean to imply that we are wedded to any particular form of psychotherapy. The entire scheme is based on the triad of sound physical medicine, education or reeducation as the case may be, and recognized psychiatric methods, all combined to treat the individual as he is and not to fit him into a scheme that is inflexible and not adapted to his particular needs. Every plan must be flexible enough to meet the individual's needs if it is to have value.

These three agencies, education, physical medicine and psychiatry, are not separated into water-tight compartments but are blended together so that one reinforces and strengthens the other. Every morning the instructors of the various classes, the social directors and the librarian meet with the psychiatrists and report the activities of the day before, making note of any special interests or aptitudes a patient may display and reporting any unusual reactions or conduct. This constantly keeps the physician in touch with the progress that each patient is making and informed of any difficulties that he may be encountering in his effort to make a good social adaptation.

The knowledge thus acquired is considered in conjunction with the information that the psychiatrist gains from the patient during his interviews, and if some of the theoretical solutions meet with failure on a practical basis the problem can again be approached from a new angle on the following day until, through this combination of therapeutic interviews and actual experience in living, the patient's problems are solved.

With this plan we have found that it has become much easier to interest our patients and keep them occupied throughout the day. They feel that there is a definite purpose in all the activities prescribed and that it is not just a matter of putting in time until the physician's next visit. We have observed that in such an environment hospital care becomes more acceptable to the patient as well as to his relatives, and they often come for treatment earlier with minor problems of maladjustment or before a frank psychosis is fully developed. We hope at some later time to report that by getting the patient under treatment and by giving him a well balanced program of training some of the frank psychoses may be prevented and the patient returned to the community.

CONCLUSION

Under this plan, when the patient does recover, the process of returning him to the community with a large segment of his life removed, out of touch with the times and conditioned to being guided and regimented is largely eliminated. The patient is never completely insulated from the normal processes of living and he is encouraged to continue making his own decisions and to develop his own initiative in our own little community. It is a small gap to step over from that community to life in the outside world.

We have purposely refrained from the use of the term "occupational therapy," because we believe that this plan embodies a much broader concept, it is, we believe, a reeducation, a training for the competition of life.

200 Retreat Avenue

ABSTRACT OF DISCUSSION

DR EDWIN G ZABRISKIE, New York I present the attitude of an outsider looking in. I have seen these earnest men hard at work on their comprehensive scheme, and, while it has been successful so far as my own experience goes, it predicates and insists on an intensive follow up of the individual patient, to prevent him from getting into a jam. Then the very looseness, or apparent looseness, of the organization at times leads to conditions that are not always best for the patient, but I believe that on the whole the plan that they have evolved is a distinct step forward and certainly is much more of a reeducational institution than any I know of around New York.

DR LLOYD J THOMISON, New Haven, Conn. For years occupational therapy, as it used to be known, has been accepted as part of the routine of care and treatment of patients in psychiatric hospitals. The objection that perhaps it had no real therapeutic value was heard from time to time. In addition, both patients and doctors objected to the limitation of crafts and brought out the point that what crafts we had were not things that would be carried away with the patient. Another objection was that it had no connection with vocational rehabilitation. Drs Burlingame and Wagner, in extending their concept of occupational therapy, have done away with these objections, and I believe that in their method there is really true therapeutic value, especially for the psychopathic personalities or the so called neuroses. I can imagine certain cases of depression with retardation in which the suffering might be made more acute when the patient is urged into activities to any great extent, but I am sure that this point is not overlooked in this program. In cases of schizophrenia in which withdrawal more and more from contact with reality seems destined, one might question whether it is right to make the patient go on in contact with reality. But there are so few who know what the destiny of a schizophrenic patient is going to be that I don't believe the objection is valid. Then, when the schizophrenic process becomes arrested, with the method given here there is a great deal of value in rehabilitating such a person. In the more progressive schools and camps, competition is being gradually eliminated. I think that competition has a definite value in education. Some years ago Dr Bryan applied kindergarten methods to some of his more deteriorated patients and obtained good results. I think that going back to the nursery school, beyond the kindergarten, might be a good idea. In reports received from the nurses in training in the Yale School of Nursing I find that after they have had some experience in nursery school work they find that they can do much better work with the psychiatric patients. Nursery school techniques are not techniques to be used only with 2, 3 or 4 year olds or deteriorated persons but in everyday life, and I can imagine that is more or less the technique used by the personnel in this particular setup. I have seen the developments of the past four years in Hartford and I feel that it is one of the main contributions to psychiatry during that time.

DR CARL P WAGNER, Hartford, Conn. I want to comment on some of Dr Zabriskie's remarks with regard to the latitude of courses of training. As he says there are advantages and disadvantages to this and Dr Burlingame and I agree that the advantages do outweigh the disadvantages. We try to study the patient from every standpoint, physical, psychologic and psychiatric. After this, we make an effort to find something that seems to fit the particular individual. To do this it is imperative that there be courses touching a wide variety of subjects. The chart was illustrative of a boy who was very poor in arithmetic; it was the thing he had failed in at school and it was the thing that stood in his way. It was for that reason that mathematics was emphasized in this schedule. Once it is decided what courses the patient is to follow, there is a certain degree of rigidity. There are certain occupational rules, certain social standards, that all are supposed to adhere to in business and social life, and once the patient has made up his mind he should be expected to adhere to it. To rehabilitate a psychiatric patient we think that it is equally important that the fluctuation from one interest to another should be held within certain limits and that his efforts should if possible be concentrated in one direction. Dr Thompson remarked that occupational therapy, of course, has been accepted for years,

and we don't think that it has to be defended. There are many types of occupational therapy that have become associated with mental disease and forms of occupational therapy that have lost their value as hobbies for a normal person. If occupational therapy is going to be used as something to distract a patient why not at the same time give the patient a hobby he can take along home, fill his idle moments with and keep him from going back to the depressive preoccupations or schizophrenic fantasies? Each case must be studied. If the program of activity seems to be driving the schizophrenic patient, who is withdrawing further into his depression, the program has to be altered but the whole scheme must be flexible and must be of a nature to meet the problems of the individual patient. In like manner, if it should drive the schizophrenic patient further into his preoccupations, that too can be corrected by altering the program and trying to find something that will stimulate a spark of interest as a nucleus and from that nucleus develop and eventually broaden the individual's interest.

THE RELIABILITY OF SPUTUM TYPING
AND ITS RELATION TO SERUM
THERAPY

JESSE G M BULLOWA, MD

Clinical Professor of Medicine, New York University Medical College
Visiting Physician, Harlem HospitalWITH THE TECHNICAL ASSISTANCE OF
MILDRED SOMMERS AND EDWARD TURNER
NEW YORK

The serum treatment of pneumonia was first attempted more than forty years ago by Klemperer in Berlin and Elser in New York but could not be successfully introduced until different types of pneumococci were recognized and patients suffering from pneumonias due to specific types were treated with homologous serums.

RECOGNITION OF TYPE

Possibly the most important recent advance in the serum treatment of pneumococcal pneumonia is the more rapid determination of the invading type. This has been accomplished by the introduction and popularization of the direct method of sputum typing based on an observation of Neufeld,¹ published in 1902, that in the presence of homologous serum the capsule of the pneumococcus became swollen.

This method was proposed by Armstrong² three years ago, although it had already been used intermittently by Ettinger-Tulczynska³ in Neufeld's laboratory for a number of years. She employed a dye to outline the capsule and used rabbit's serum. Goodner is to be credited with seeing the importance of the method and Sabin⁴ with demonstrating its value in an ample series of cases at Bellevue Hospital, and with pointing out that diagnostic horse serums, commonly in use in America, were unsuitable.

Read before the Section on Pathology and Physiology at the Eighty Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1935.

This study was in part supported by the Metropolitan Life Insurance Company. The Research Laboratory of the Department of Health, New York City (Dr. William H. Park, director) supplied most of the typing serums employed in these studies. Miss Georgia Cooper checked many cultures. The Lederle Laboratories, Inc. generously gave typing serums for the study.

⁴ Sabin, A. B. Immediate Pneumococcus Typing. *Directly from Sputum by the Neufeld Reaction*. *J. A. M. A.* 100: 1584-1586 (May 20) 1933.

The Neufeld test is performed by mixing a droplet of the sputum with homologous rabbit serum (this may contain the standard alkaline methylene blue dye), permitting the specimen to stand a few minutes and then observing it under the oil immersion lens. When mixed with homologous serum the capsules are swollen and when mixed with heterologous serum they are unchanged. Serums may be pooled into several

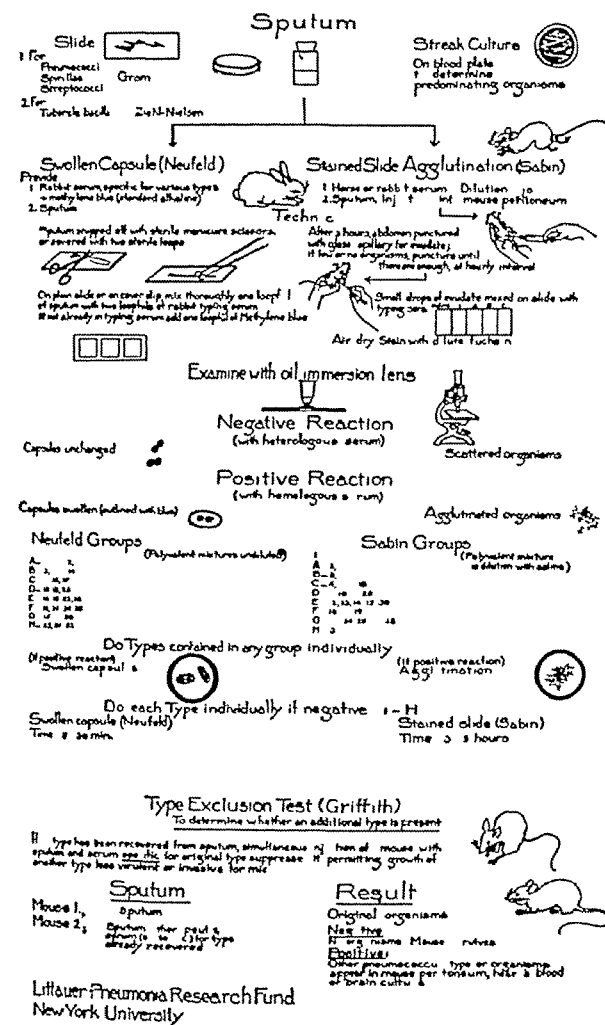

Chart 1—Pneumococcus typing Steps in the swollen capsule (Neufeld) and stained slide agglutination or Sabin technic Group typing and type exclusion

groups so as to save time in typing the upward of thirty types that are now recognized, as shown in chart 1. If a reaction is found in any group, the separate types are studied to find the one responsible for the swelling. This method may also be applied to exudate obtained from the peritoneum of a mouse or when very few organisms are present in cultures. The organisms may be so few that it would be difficult to demonstrate agglutination. The presence of more than one type and the proportional distribution of two types may be determined by this direct examination of the sputum.

The Neufeld reaction has been obtained in sputums that have been preserved several days in the icebox and even in some inadvertently preserved in solution of formaldehyde, tricresol or phenol. The pneumococci in such sputums may not be viable as tested on

mice and accordingly are unsuitable for the mouse technic of Avery or of Sabin. It has also been successfully used by us on the swallowed sputum aspirated from the stomachs of infants.

One hundred successive recent Neufeld examinations of sputum were found to give 76 per cent positive results in our laboratory. This is precisely the frequency of success of Cooper and Walter.⁵ The distribution of the types found is given in chart 2, as well as the results obtained by the Sabin technic from twenty-four sputums that were negative on Neufeld examination after painstaking effort. Though little equipment is required for the test it requires skill, and early negative results should not discourage those beginning to use it.

The stained slide agglutination method of Sabin has the advantage over the Neufeld method that a very few pneumococci in the sputum may multiply in the peritoneum of the mouse, while interfering organisms perish. The typing of the peritoneal exudate may be checked by the organisms causing septicemia in the mouse, as found in broth cultures from mouse heart or brain. Such small amounts of material are required that in three or four hours there may be sufficient exudate to type for thirty-two different types (chart 3).

By these microscope methods of typing we have found that the unclassified organisms constitute at present (1933-1934) only 12 per cent of the pneumococci encountered among adults (chart 4). A report of "group IV" or x type should not be accepted without question and without a second attempt to classify such a pneumococcus either by direct typing of sputum, mouse inoculation (including mouse blood or brain culture) and the patient's blood or lung suction.

The advantages of typing by the microscope method are as follows:

1. The pneumococci are seen. Failure to obtain a precipitate in the Avery method may be due to a total

Chart 2—Pneumococci pneumoniae in adults 1933-1934 typing by Neufeld capsule swelling in 100 consecutive patients types obtained by Neufeld seventy six types obtained by Sabin twenty four

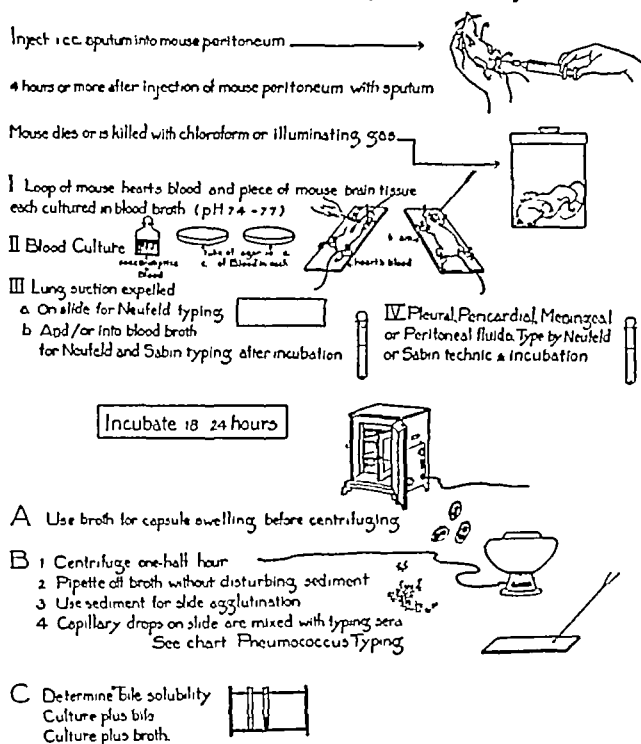

absence of pneumococci in the peritoneal exudate and might be reported as pneumococcus group IV unless care is taken to study the peritoneal exudate microscopically.

2. Because very small quantities of material are needed the peritoneal exudate from a single mouse

5. Cooper, Georgia M., and Walter, Annabel W. Application of the Neufeld Reaction to the Identification of Types of Pneumococci. *Am J. Pub. Health* 25: 469-474 (April) 1935.

is sufficient to type for all the types of pneumococci, with a recheck of the typing, if necessary

3 It is possible to make the very important differentiation directly between type II and atypical type II or type V, and type III and the so-called atypical III or type VIII, without the delay for restudy with dilu-

Chart 3—Typing from mouse heart or brain to determine cause of mouse septicemia

tions of the typing serum. These distinctions are not academic but of great practical interest in prognosis and therapy.

The amount of infected pulmonary mucus required for type determination is very small, and frequently sufficient may be collected on a swab after coughing, especially after the patient has been turned on his side, with the affected side uppermost, and urged to cough. Sometimes the mucus adheres to the pharynx or palate and may be removed with an applicator and either directly examined by the Neufeld technic or, after incubation in broth for three hours, injected into the peritoneum of a mouse and typed by the Sabin method.

The character of the sputum in types I and II and its relation to success in obtaining a type was analyzed and it was found that the type might be obtained from all varieties. Sputum flecks obtained by pharyngeal swabbings gave the correct type in 112 out of 154 cases, or 73 per cent. In twelve, or 8 per cent, they gave an incorrect type and in thirty, or 19 per cent, no type at all.

In the presence of clinical consolidation, organisms obtained from the sputum are usually responsible for the pneumonia. Good sputum (which may be very scant and frothy) when the type can be determined gives a high correlation between the types obtained from it and those obtained by the lung suction and/or blood culture. Since pneumococci formerly included in group IV are frequently found in the throats of individuals in apparent health, the importance of discovering these organisms in sputum recovered from patients

with pulmonary consolidation has been doubted, and their etiologic relationship with lesions in the lungs has been questioned.

Two methods of determining the validity of the type obtained from the sputum were available. One was to correlate the recovery of the organism from the sputum with that obtained by transthoracic puncture of the consolidated area, and the other was to correlate the sputum organism with the one recovered from the blood stream. The latter source is subject to the possible slight objection that the source of the blood invasion might be other than lung. A positive result from material aspirated from the lung has greater value over that obtained from the lung through the mouth only in that it is not likely to have been aspirated into the trachea or to be contaminated with mucus from the upper respiratory passages. Certain types of pneumococci are more frequent in the upper respiratory passages than others, but almost all the types from I to XXXII (described by Cooper) have also been recovered by us on lung suction. Negative suction in non-pneumonia patients and from the uninvolved area in pneumonia patients, as well as the failure to recover them from unconsolidated lung in recent postmortem lung suction, show that the normal lung does not usually contain viable pneumococci.

A negative lung suction with our technic may be caused by several circumstances besides lack of skill on the part of those attempting it. Success in securing positive cultures from lung suction has varied with different resident physicians, depending on their skill in locating the maximum consolidation and in their limitation of the indication for lung suction. Some have secured as much as 50 per cent of growths. Physical signs and radiographic evidence of consolidation may be misleading. Even in consolidated areas, few or no viable organisms may be present. There is frequently considerable edema about the main focus, which may not be heavily infected.

We employ a needle of very fine bore and if it becomes occluded in penetrating the thorax we may obtain no lung exudate and consequently no growth. In most instances, when the contents of the syringe are discharged into the broth for culture, a turbid cloud is seen. When the needle is introduced into the lung,

Chart 4—Decline of the x group

Pneumococcus type I lend only slight support to this view, for we found pneumococci in approximately one half of the cases on all days with very little less than half on the seventh and eighth. Twenty-six positive and twenty negative cultures were obtained on the fourth day (chart 5).

6 Thomas H. M. Jr., and Parker Frederic Jr. Results of Anterior Lung Punctures in Lobar Pneumonia. Their Bearing on the Mechanism of Crisis. Arch. Int. Med. 26: 125-132 (July) 1920.

In order to learn how much reliance could be placed on sputum examinations, we analyzed (1) lung suction on 1,255 adult patients, a total of 1,467 times, and (2) our experience with determining the type on 1,000 patients with the clinical and laboratory diagnosis of pneumococcal pneumonia. In almost all cases the diag-

quent blood culture or from another source, e g, chest fluid or postmortem cultures. The type was obtained first from lung suction in 146 of 479 positive lung suction, or 30 per cent. In 11 per cent of all cases in which lung suction was done the type of pneumococcus responsible for the pneumonia was first ascertained from the lung suction.

There were 506 cases in which there was evidence supporting the correctness of the sputum typing. The

Chart 5—Pneumococcus type I in adults July 1931 July 1934. Two hundred and eighteen lung suction positive and negative arranged according to day of disease lung suction was performed

nosis of pulmonary consolidation was confirmed by radiographic examination and by the clinical course.

1. In the lung suction series, every type was obtained by lung suction during life excepting type XI, XV, XXV, XXVII and XXIX. In some instances it was

type from the sputum agreed with that obtained from the blood or by direct lung aspiration or both in 474, or 93.7 per cent. There were thirty-nine cases in which an additional or different type was involved, but seven of these cannot be said to be definitely contradictory, because there were six in which, though sputum differed from lung suction, the sputum agreed with the blood culture and one in which, though the sputum was different from blood culture, the sputum agreed with the lung suction. Table 1, giving the data, divides the cases into those with sputum not confirmed and those with sputum confirmed.

Lung suction was positive when the blood cultures were negative in 326 of 474 confirmed cases, or 66 per cent, and the blood cultures were positive with negative lung suction in forty-six cases among 211 bacteremic cases, or 21.8 per cent. In thirty of the latter instances

Chart 6—Source of type in 1,000 pneumococcal lobar pneumoniae

† Sputum not confirmed by lung suction or blood culture in thirty-two cases (6.3 per cent).

the first evidence of etiologic type because the responsible organism was not found in the peritoneum of the mouse injected at the same time that the lung suction was made. In such cases the pneumococcus type was recovered eighteen hours later from the heart or brain of the mouse, or from a second sputum from a subse-

the blood cultures were taken at the same time as the lung suction. In this series, more than one organism was found on lung suction in seven cases.

2. To check the results from the lung suction study, 1,000 consecutive cases of pneumococcal lobar pneumonia of determined pneumococcus type were studied to learn how often the correct type was obtained from the sputum. The cases involved in the two studies overlap.

Five hundred and forty-eight cases yielded a specific type that was confirmed in the way shown in table 2.

Four hundred and fifty-two cases were not confirmed for the reasons given in table 3.

Among 365 cases in which a type was not obtained from the mouse peritoneum, in 204 cases it was obtained from mouse heart or brain.

Among the 1,000 cases the pneumococcus type was obtained in 710 from first sputum, 496 from the peritoneum and in 214 from the mouse heart or brain culture. In sixty it was obtained from the second sputum and in 230 from other sources (chart 6). Thirty-one different types of pneumococci were found distributed as shown in table 4.

In this series of 1,000 cases there were only thirty-three instances of discrepancies in the type obtained by various means. This is shown in table 5 and in chart 7. The types obtained from lung suction and patient's blood culture have been regarded as etiologically

related to the disease in the patient for obvious reasons. The type obtained from the mouse's heart, when different from that obtained from the peritoneum, has been given precedence, but in two of twenty-two con-

firmed cases this was incorrect. In fourteen cases the correct type was obtained by lung suction, in four cases from blood culture, in one case from chest pus and in one case from a gluteal abscess. In eight cases there

was divergence in the results from two sputums, in three a single sputum gave two types.

From the data in this group of cases we found that in 445 cases (with evidence from a different source than the sputum) the type obtained from it was responsible for the illness, and that in thirty-three cases there was either a significant divergence or doubt because of an added type (table 6). In only twenty-two of these cases was the sputum type incorrect or misleading. The eleven remaining cases, though

7 Because of lack of space this chart has been omitted from THE JOURNAL. The complete article appears in the authors' reprints.

divergent in the results obtained in mouse peritoneum and mouse heart, were not definitely incorrect, they may have been double invasions with one type unconfirmed. Even if the entire group were to be considered erroneous there would be 488 cases in which the type obtained from the sputum was confirmed and thirty-three cases in which it was incorrect or misleading, or 57 per cent. This is approximately the percentage obtained from the lung suction study, which included cases observed over a much longer period.

The development of agglutinins in pneumonia patients, if they have been previously absent, supports the reliability of sputum typing. It has not been

TABLE 7—Relation of Agglutinin Detection to Mortality in Pneumococcal Pneumonia Type I Sixty Four Serum Treated Bacteremias 1929-1932

stressed because stimulation of antibodies may occur from foci in the upper respiratory passages. A group of recovered non-bacteremic non-serum cases in which agglutinins were found after they were not detected on a previous examination were selected from the records. In the forty confirmed cases, agglutinins were found in twenty-six, or 65 per cent, of the cases, in seventy-seven unconfirmed cases they were present in forty-two cases, or 54 per cent, 11 per cent fewer instances.

Although sputum typing is 93 per cent correct, blood cultures should be taken in all cases of pneumonia. A recent study of the influence of blood invasiveness on mortality in different types⁸ emphasizes the importance of blood invasion in prognosis and the variation in invasiveness of the different types. The mortality rate and the incidence of bacteremia were approximately the same in almost all types. Rosenbluth⁹ and Cecil and Plummer¹⁰ had previously made similar observations.

Chart 8—Mortality in pneumococcal pneumonias, bacteremic and non-bacteremic cases, 1928-1934

A study of our experience during six years, embracing 2,058 cases (chart 8) shows the incidence of death in the bacteremic and nonbacteremic cases for nineteen different types. It is seen that the occurrence of

8. Bullowa J C M and Wilcox, Incidence of Bacteremia in the Pneumonia and Its Relation to Mortality Arch Int Med 53: 558 573 (April) 1935

9. Rosenbluth M B Relation of Bacteremia in Lobar Pneumonia to Prognosis and Therapy J A M A 90: 1351 (April 28) 1928

10. Cecil R L and Plummer Norman Pneumococcus Type II Pneumonia J A M A 98: 779 (March 5) 1932

bacteremia is a crucial factor in determining the fate of the pneumonia patient. The effect of serum on the invaded and the noninvaded cases of four types, I, II, VII and VIII, is given for comparison and shows a definite reduction of death rate, greatest in types I and VII.

The following considerations show that the serum treatment of the pneumonias is a specific treatment depending on the correctness of typing. Cases in

Chart 9—Littauer Pneumonia Research Fund of New York University Harlem Hospital Station Adult pneumococcal pneumonias types I, II, VII and XIV bacteremic incidence (black column) and total mortality (black and white striped column) in treated and untreated cases

which the pneumococcus type has been different from the type responsible for the illness, as the result either of errors or omissions to obtain the correct type, have not been benefited by the homologous serum when it has been used.

At Harlem Hospital, patients admitted to the pneumonia service with definite consolidation are given two doses of serum for types I and II pending the determination of the type from the sputum, blood or lung. In those cases in which the pneumonia is due to type I or II there has been a definite improvement and a lowered incidence of bacteremia, but other patients have been neither benefited nor harmed. This is shown in chart 9.

When the correct type is being treated there is a quantitative relation between the amount of serum used and the onset of defervescence. Large doses are more effective in severely ill patients than small doses. This was shown in numerous observations. When the amount of antibody administered is measured by the appearance of agglutinins in the blood stream, it is found that the recovery rate in type I patients is higher in those revealing it than in patients in whom it has not been demonstrated, as shown in table 7.

Finally, the nonspecific shock reactions with chill and rise of temperature and subsequent fall are rarely elicited with well refined serums, the administration of serum is frequently followed by a fall of temperature, pulse and white blood cells, in crises induced early in the disease. The natural termination is thus simulated.

CONCLUSIONS

1. The pneumococcus obtained from the sputum of patients ill with pneumonia is the type responsible for the disease in over 93 per cent of the cases in which confirmatory evidence was obtained by blood cultures, lung suction or metastatic foci.

2. The correct type is obtained from the first sputum in 71 per cent of the cases, from the peritoneum in

49.6 per cent of the cases, from the mouse's heart or brain in 21.4 per cent of the cases, and from the second sputum taken one or two days later in 5 per cent.

3 The Neufeld reaction gave the pneumococcus type in 76 per cent of cases.

4 The λ group, or "type IV," is found to be responsible for only 1.2 per cent of cases.

5 The incidence of bacteremia and the death rate are roughly parallel in most types of pneumococcal pneumonia.

6 Serum reduces the death rate in bacteremic and nonbacteremic cases and prevents bacteremia in some types of pneumococcal pneumonia.

7 The action is specific and not a general protein therapy.

ABSTRACT OF DISCUSSION

DR WILLIAM H PARK, New York. It seems strange that physicians do not use good antipneumococcus therapeutic serums for the newer types when they are available. So far as I know, of the frequent types, type III is the only one in which serum may not be of benefit. In the Children's Division at Bellevue Hospital I have a bacteriologist who has been definitely working with the physician in charge of the children's service, and her results have been remarkable. Miss Vinograd has found that in 96 per cent of 106 cases the Neufeld reaction gave apparently a correct result and that the completion of the test never took more than two and a half hours, and frequently only half an hour. When one thinks of the previous mouse tests, which took twelve hours or more, and the new improved Sabin test, which took from four to eight hours, one is impressed by the speed of the Neufeld test. With the Neufeld test, however, as Dr Bullova said, the technician has to have considerable experience always to escape making mistakes. Even now Miss Cooper, who would probably rank among the first at making these tests, obtains occasionally from the hospitals reports of types of pneumococci of which the examiner is not quite sure and, on testing, she finds a different type. In the first place she has shown that one should not use immune horse serum but rabbit serum. One has to learn in a sort of uncanny way, to decide whether the material is sufficiently good to test or not. When I stated that in 96 per cent of the cases Miss Vinograd had a correct result, that doesn't mean that in 96 per cent she found pneumococci because in some cases the pneumonia was not due to the pneumococcus. Most examiners with some months or a year of experience get quick and accurate typing results.

DR S W SAPPINGTON, Bryn Mawr, Pa. My results confirm those of Dr Bullova with respect to the reliability of sputum typing. The Neufeld method made typing easy and rapid, but proof was needed that the pneumococcus type found in the sputum was the causative organism. This proof has apparently been found in the type recovered by the simple and satisfactory procedure of lung puncture or suction. In a series of sixty cases of lobar pneumonia, Dr Favorite and I obtained fifty-four, or 90 per cent, positive cultures by lung puncture, 50 per cent within six hours. Fifty-one of these cases were pneumococcal and in forty-four the sputum was available for typing. In nineteen, the type was not determined for want of appropriate typing serums. In the remaining twenty-five sputums, the type ascertained was the same as that of the corresponding lung culture. In other words, when we were able to type both lung culture and sputum there was a 100 per cent agreement. In twenty-four of these, the agreement was determined on the first typing, in one case it was determined on a second attempt. Seventeen blood cultures were done, four were positive and these four agreed in type with those of the lung and sputum. There were three pneumococcal empyemas in the series, here the pleural, lung and sputum types agreed. Our observations, therefore, support the reliability of sputum typing.

DR JESSE G M BULLOWA, New York. Our results at Harlem Hospital are not quite as bad as the difference between 93 and 76 per cent would seem to indicate. My 76 per cent

positive Neufeld results are in cases in which a pneumococcus was later obtained, and (to make the Bellevue statistics comparable) the sixteen cases in which no pneumococcus was obtained by the Neufeld or other method must be subtracted from 93, which would give 77 per cent. The results with type I serum, when considered by the day of illness on which treatment is begun, are almost as good as the results for diptheria. Charts showing this are in my exhibit.

Clinical Notes, Suggestions and New Instruments

TRANSIENT HEART BLOCK IN A DIABETIC PATIENT DURING AN ACUTE CORONARY THROMBOSIS

ELTON R BLAISDELL, M D PORTLAND, MAINE

A woman, aged 56, admitted to my clinic, Dec. 31, 1930, complained chiefly of precordial pain on exertion. The past history was unimportant except for obesity of twenty years' duration. The present illness began in February 1930, at which time she noticed a gradual loss of weight and strength. A few weeks later she was conscious of substernal discomfort when walking up stairs and in May consulted a physician, who made a diagnosis of diabetes mellitus and angina pectoris. A diet was prescribed, and restriction of both physical and mental activities was advised. Although the patient refrained from walking outdoors and reduced her social activities to a minimum, the anginal pain became more troublesome. The urine always contained sugar in spite of strict adherence to the diet. The use of insulin had been discouraged because it was feared that it might aggravate the anginal pain.

On admission to the hospital the patient was healthy looking and of normal weight. The fasting blood sugar was 228 mg and the urine contained 1 per cent sugar. The blood pressure was 130 systolic and 70 diastolic. The circulation in the extremities was good. No heart murmurs were heard and there was no evidence of coronary artery disease in the electrocardiogram. She spent ten days in the hospital and was discharged on a diet of 70 Gm of protein, 100 Gm of carbohydrate and enough fat to make 1,700 calories, with 35 units of insulin daily. This proved to be a maintenance diet, as the weight has not varied more than 8 pounds (3.6 Kg) since that time.

The patient was seen about once a month until March 1932. During this time no change was made in the diet but the insulin was reduced gradually to 4 units twice daily. Hypoglycemia was prevented by a gradual reduction in insulin and blood sugar readings just before lunch, ranged from 110 to 130 mg. She was advised to remain quiet for thirty minutes after each meal. There was almost complete relief from substernal pain during the summer of 1931 although exercise was confined to short walks on level ground. In the late fall the pain returned without any apparent reason. Aminophylline and a preparation of theobromine and phenobarbital given three times a day gave no beneficial effect. The nitrates were equally ineffective in preventing the attacks. Anginal pain would occur on the slightest exertion and it was frequently necessary for the patient to take three tablets of glyceryl trinitrate ($\frac{1}{100}$ grain or 0.6 mg) before the attack would subside. The paravertebral injection of alcohol was suggested but the patient preferred to remain more or less of an invalid, hoping that she would again feel better when summer came.

At 4 p m, March 14 1932 she had a severe substernal pain followed by vomiting and collapse. When I saw her twenty minutes later, the chest pain was evidently excruciating and she was having frequent short attacks of syncope. The skin was cold and moist. The apex rate was 40 and only faintly audible, and the blood pressure readings were not obtainable. The pain was partially controlled with one-half grain (0.03 Gm) of morphine. A rectal suppository containing 3 grains (0.2 Gm) of barium chloride was given and both insulin and nourishment were omitted for the evening.

This case was presented before the clinical session of the Maine Medical Association Portland Oct 5 1934

When she was seen the following morning, the blood pressure was 110 systolic and 70 diastolic. Morphine was given twice during the night for pain. The heart rate was the same and a pericardial friction rub could be heard at the apex. An electrocardiographic tracing showed a 2:1 block and inversion of the T wave in leads 2 and 3. The urine gave a red reduction for sugar with Benedict's test. The usual 4 units of insulin was given and four hours later the blood sugar was 400 mg. Only a small portion of the regular diet was taken during the first week, but the 4 units of insulin was administered night and morning, as the urine continued to show a large amount of sugar. The substernal pain disappeared after the first twenty-four hours and the patient did not complain of it during the remainder of her confinement in bed. During the second day, an unsuccessful attempt was made to restore the normal heart rate with atropine sulphate, $\frac{1}{100}$ grain was given hypodermically every four hours for three doses. She was given 5 grains (0.3 Gm) of barium chloride by rectum on three successive days. The evening of the third day, the heart rate suddenly increased to 80 per minute and the fainting attacks, which had been occurring since the onset of the acute illness, subsided with the increased rate. No electrocardiogram was taken at this time, but clinically the heart block had disappeared.

In the beginning of the second week the diet was increased to 60 Gm of protein, 100 Gm of carbohydrate and enough fat to make 1,500 calories. The insulin was increased to 12 units a day, and four days later the 11 a. m. blood sugar was 170 mg with a decrease in the urinary sugar. The blood sugar

Electrocardiogram taken March 15, 1932. 2:1 block with a PR interval of 0.40 second indicating disturbance of circulation in junctional tissue. Ventricular rate 48, auricular rate 96. Every other P wave in leads 2 and 3 buried in ST interval. Inverted T wave in leads 2 and 3.

gradually fell to 130 mg and was kept at approximately this level with 10 units of insulin daily. An electrocardiogram taken on April 22 showed a normal PR interval but the T wave in leads 2 and 3 was still inverted. After seven weeks of bed rest, the patient was advised to begin getting up, but she was so afraid of a recurrence that it was not until three weeks later that she would get into a chair.

The diet was now increased to 1,700 calories, the carbohydrate was increased to 200 Gm and the fat decreased to 69 Gm, with an insulin requirement of 6 units daily. It was hoped that the increase in carbohydrate would be beneficial to the coronary artery sclerosis. This may or may not have been responsible for the improvement in the patient's condition. However, during the past two years she has been very active socially and has done light work in her flower garden. Her only discomfort is a sense of substernal burning when she walks up an incline. By refraining from this, no medication is necessary, with the exception of insulin. Recently the insulin was discontinued, but this was followed by an elevation of blood sugar, and insulin was again started. The systolic blood pressure has not been less than 130 for the past two years. An electrocardiogram taken, Jan 23, 1935 was essentially normal and closely resembled the one taken before the attack.

COMMENT

Many observers have called attention to diabetes mellitus as being a frequent etiologic factor in producing coronary artery sclerosis. Although the symptoms of coronary artery disease appeared in this patient very shortly after diabetes was discovered and too soon for the disturbance of metabolism to have played a part in the etiology, it is possible that a mild

diabetes may have been present for several years before the onset of acute symptoms.

During the first few days following an acute coronary thrombosis, a previously well regulated diabetic patient may develop a high blood sugar and urinary sugar. If the disturbance of carbohydrate metabolism has been mild before the attack, no attempt should be made during the first week to control the glycosuria with insulin, as it will usually disappear within a few days. In an insulin patient in whom the diet-insulin ratio is known, relatively small doses of insulin may be given. Too much stress cannot be placed on the cautious use of insulin during convalescence from acute occlusion of the coronary artery. An insulin reaction is more than likely to be fatal, and a sudden drop in the blood sugar level, even though it does not go below normal, may produce cardiac embarrassment.

Transient heart block appearing during the course of acute coronary thrombosis decreases the likelihood of recovery from the attack. In Levine's¹ series of 145 cases there were two patients with complete block and eleven with partial block. Both patients with complete block and six of those with partial block failed to survive the initial attack. According to White,² the descending branch of the left coronary artery is the area most commonly affected by sclerotic changes and by thrombosis. As the auriculoventricular node, in the majority of cases, receives its blood supply from the right coronary artery, it is not difficult to explain the relative rarity of transient heart block in acute coronary thrombosis. Parkinson and Bedford³ were the first to demonstrate that it was frequently possible to differentiate between right and left coronary artery occlusion by means of two distinct types of T wave changes in the electrocardiogram. Inversion of the T wave in leads 1 and 2 would indicate occlusion of the left coronary artery, while inversion of the T wave in leads 2 and 3 would indicate involvement of the right coronary artery.

The case presented illustrates the sudden increase of blood sugar that may follow an acute coronary thrombosis and the slight variation in insulin dosage necessary to control the diabetes after the first week. Another interesting feature was the sudden development of a 2:1 heart block that persisted for three days, during which time frequent fainting attacks occurred in spite of a definite decrease in pain and a return of the blood pressure to nearly a normal level after twenty-four hours. It is possible that periods of complete block may have been present during this time. The inversion of T and T_s would suggest an occlusion of the right coronary artery and agrees with the observations of various investigators, namely, that heart block in acute coronary thrombosis is usually caused by interference of circulation in the right coronary artery.

The effect of barium chloride on the heart block in this patient is open to question, as the normal heart rate may have been restored in the same length of time without barium.

Why has there been almost complete freedom from precordial pain since the acute attack? There was no continued drop in blood pressure to account for it. Could it be due to the increase of carbohydrate in the diet or, more likely, to a well established collateral circulation furnishing the heart muscle with a better oxygen supply than it had previously received through a supposedly sclerotic coronary artery?

Energy in Certain Foods—The following are the approximate energy values of a few typical foods in calories per pound: bread, 1,200, butter, 3,500, eggs, 600, milk, 300, orange juice, 230, macaroons, 1,900, mince pie, 1,300, potatoes, 380, sugar, 1,800. As foods are "fattening" in almost exact proportion to these energy values it will be seen that where it is desired to keep down the body weight there is much more to be gained by restricting the fats, sweets and pastries rather than milk, fruit and vegetables.—Sherman, H. C. Food and Health, New York, Macmillan Company, 1934.

Special Article**GROWTH, NORMAL AND ABNORMAL**CLINICAL LECTURE AT ATLANTIC CITY
SESSION

WILLIAM BOYD, MD, FRCP (LOND)

Professor of Pathology, University of Manitoba Faculty of Medicine
WINNIPEG, MANIT

Growth is the most fundamental of all biologic processes and one of the most mysterious. Julian Huxley has defined it as "the self multiplication of living substance," and it is fundamentally a matter of multiplication of units rather than of increment of size. An elephant is larger than a mouse because the cells of which it is composed have the power of multiplying more continuously than those of the mouse. The cell units of the large animal are no bigger than those of the small one. When a cell divides into two the daughter cells are at first smaller, soon they attain the original size, but no larger. Lorrain Smith¹ in his delightful book on growth describes the process of growth as "a procession of cell units in which each member in its turn disappears in producing its successors. The units increase in number as the procession moves onward. Generation succeeds generation until the tissue is formed."

Growth is gradual, but cell division is not gradual. It takes place suddenly and is completed in the space of an hour, "one crowded hour of glorious life," as Sir Walter Scott would call it. It is obvious that the cells of an organ do not all divide at the same time, otherwise the liver would double its size in an hour. The cells that are not dividing are functioning, those which are dividing have no time for work. At a certain stage of development some cells, such as those of connective tissue, are capable of unlimited and inexhaustible growth, provided the environment is ideal, the supply of food is abundant, and the cells are not burdened with work. The power of growth varies at different age periods. It is enormously great in the early months of fetal life, for a single ovum has, with the able assistance of a spermatozoon, to develop into an 8 pound (3.6 Kg.) baby in the short space of nine months. That, of course, is nothing to what some animals can do, for R. C. Andrews removed a 25 foot baby weighing 8 tons from a sulphur-bottom whale. This remarkable rate of growth is not necessarily dependent on conditions of intra-uterine life, for, as Wetzel² points out, a premature infant of 1,000 Gm may double its weight in the next forty-four days in order to catch up with a normal baby. At the end of the period of infancy there is a comparative rest in what Wetzel calls the motion of growth, a period of minimum rate of gain, rate of growth, and rate of heat production.

Though growth ceases in adult life, the cells still retain their capacity for growth. Were it not so, repair would be impossible. Perhaps malignant neoplasia would also be impossible.

CONTROL OF GROWTH

The factors that govern and stimulate growth are so numerous and complex that they can be little more than mentioned in this necessarily brief survey. Among these are embryonic tissue extract (so essential in tissue cultures), thyroxine, the anterior pituitary growth stimulating factor, and certain vitamins. In addition there is that obscure and elusive principle which for want of a better name may be called the vital spark, that intangible something which enables living matter to dip down into the dead stuff of the inorganic world and build it up into its own vital protoplasm and, by utilizing the energy so obtained, accomplish the almost incredible act of self reproduction. There is, of course, no inevitable relationship between these two phenomena, and cells are known to vary enormously in their capacity for self multiplication, this depending to some extent on the degree of differentiation. For, generally speaking, growth and specialization are mutually antagonistic. Nerve cells may be regarded as among the most highly specialized in the body, and it is known that when these are destroyed by poliomyelitis or the surgeon's knife they cannot be replaced by cells of their own kind. The same is true of muscle cells. In the bone marrow, multiplication takes place in the megaloblastic and especially the normoblastic stage, the adult erythrocytes have lost this power—naturally so, seeing that they have lost their nucleus. The basal cells of the skin have unlimited power of multiplication, which is no longer shared by the cells of the surface that have become specialized to perform their particular function of protection. It is evident that the great controller of growth is differentiation.

The last two examples raise a question which is seldom asked but is singularly difficult to answer. When an adult cell divides into two, the daughter cells are pictured as being identical in every respect, but in the examples of the skin and the marrow this can hardly be so, for one of the daughter cells must remain in situ while the other becomes cornified and finally changes into a squamous surface cell or loses its nucleus and develops into an erythrocyte. The daughter cells, so apparently alike, are evidently different, for one is taken while the other is left. In a malignant tumor this distinction is lost, and all the daughter cells are alike.

Among the factors necessary for growth, food is the most important. The relation between food and growth is far too complex a subject to be considered here, but reference may at least be made to the growth-stimulating substances known as vitamins. The best example of a vitamin-deficiency disease leading to stunting of growth is rickets, in which the lack of vitamin D interferes to such a degree with the development of cartilage into bone that the child for a time at least may be a rachitic dwarf. Growth is also dependent on an adequate supply of vitamins A and B₂. I shall have to return to the question of vitamins in connection with the growth of tumors.

Reference has been made to dwarfism, and an adequate survey of this subject would display as clearly as anything the extent of our knowledge and ignorance of the subject of growth. It is probable that the most important element in dwarfism is lack of the growth-stimulating hormone of the pituitary either directly from the disease of that organ or indirectly as the result of influences from the other endocrine glands. Every one knows that hypophysectomy in a young ani-

Read before the General Scientific Meeting at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1935.

2. Wetzel N. C. On the Motion of Growth. Prolegomena to the Clinical Study of Human Growth and Metabolism. J. Pediat. 3: 252 (July) 1933.

mal inhibits growth, that transplantation of gland tissue or injection of an extract of the anterior lobe will restore the function of growth, that the secretion of the acidophil cells of the anterior pituitary is the most potent regulator of skeletal growth, that hyperplasia of these cells in early life leads to gigantism and in later life to acromegaly, and that the effect of atrophy or destruction of the cells is dwarfism of various types. Hereditary dwarfism has been reported in a strain of mice in which there was entire absence of the acidophil cells.³ In the Lorain type of hypopituitarism the patient remains dwarfed as regards both stature and sex, but in other respects he is perfectly normal. In the Simmonds type there is the addition of the features of pituitary old age. Even in the Frohlich type growth is interfered with, although the adiposity and sexual dystrophy are more striking characteristics. Selye and his associates⁴ in Collip's laboratory believe that the growth of the individual tissues and organs is largely independent of the pituitary. "Apparently the function of the pituitary growth hormone is only to permit enlargement of the size of the body as a whole, with a harmonious and proportional increase in the size of all the organs."

Thyroid deficiency in early life is also associated with dwarfism, for the cretin is a dwarf physically as well as mentally. It is not safe to assume that the lack of growth is necessarily the result of an insufficient supply of thyroxine to the tissues, for it may be due to an indirect action through the pituitary. Indeed, it is not improbable that all forms of true dwarfism are directly due to pituitary insufficiency, no matter what the ulterior cause may be. The cretin can be made to grow by anterior pituitary extract as well as by thyroxine.⁵ Thyroxine hastens the metamorphosis of the tadpole into a frog, but it is a miniature frog which, like Peter Pan, never grows up. The thyroxine, although speeding up a certain phase of development, has restricted the final limit of growth.

A form of lack of growth difficult to explain is that known as renal dwarfism. Here some form of chronic nephritis in childhood is associated with a remarkable lack of skeletal development and in many cases with osteoporosis, deformities at the epiphyses and bowing of the shafts. The essential biochemical feature is an inability of the kidney to excrete phosphorus, but what the relation of the phosphorus retention is to the lack of growth is at present a mystery. The cases described by Byrom Bramwell as pancreatic infantilism show a similar lack of development. Sometimes the cause of the lack of growth is still more obscure, as in a case that I recently saw at the Children's Hospital in Winnipeg, where a normal amount of growth had taken place in utero, but an increase of only 1 inch (2.5 cm.) in length had occurred in the six months following birth, as shown by roentgenograms of the bones, although the viscera had grown to a normal degree. The only abnormality revealed by a most thorough postmortem examination by Dr. Bruce Chown was absence of one half of the posterior lobe of the pituitary, the acidophil cells of the anterior lobe were present in normal amount. Achondroplasia affords another well known example of stunted stature for which at present no explanation can be offered.

I shall now return to some of the more fundamental problems of growth from which I have been diverted by the intriguing subject of dwarfism. The phenomenon of repair is of such universal occurrence that it is taken as a matter of course, and one seldom pauses to inquire why cells that have been sleeping peacefully for years (and surely one might describe the cells of adult connective tissue as sleeping) should suddenly awake to an active life of growth and reproduction merely because some of their neighbors have been destroyed by the surgeon's knife. This problem is more easily studied in tissue culture, where the conditions of the experiment can be simplified to the utmost, rather than in the clinical patient or the experimental animal. By means of this method it has been possible to show that, when fibrous tissue and other cells are destroyed, growth-stimulating substances are liberated, and that it is the action of these which brings about the renewed growth and repair of tissue without which the surgeon's art would be impossible. According to Hammett, the sulphhydryl radical -SH is present in all actively dividing tissue, both animal and vegetable, and practical application of this knowledge has taken the form of the use of thiocresol to stimulate the process of healing in extensive wounds, bed sores and the like.

INFLUENCE OF ENVIRONMENT

The method of tissue culture has thrown a certain amount of light on some of the fundamental problems of growth, particularly the influence of environment. When tissue cells, particularly cells of embryonic tissue, are placed in a suitable culture medium which insures a continuous supply of food and growth-stimulating substances, they will grow and multiply far beyond the life span of the animal from which they were taken. Indeed, in some cases they have continued to grow indefinitely, so that they appear to have put on a kind of immortality. Everything in this world can be bought with a price if one is prepared to pay that price, and it would appear as if immortality were no exception. But the price may be too heavy. In this case it involves the sacrifice of all hope of development and differentiation. When the tissue is removed from its environment, which apparently provides it with the stimulus to differentiate, it has no work to do and does not have to provide itself with food, so that it can devote all its energies to reproduction. The influence of environment on specialization is well exemplified by the work of Drew, who found that the parenchymatous cells of an organ failed to differentiate in pure culture but that this occurred readily when connective tissue cells were added to the culture. When this was done in the case of renal epithelium, well formed tubules were produced, whereas, without the appropriate stroma, growth merely resulted in a confused mass of cells. It would appear as if old age was not a property of the cell itself but of the environment in which it passed its life. It is natural that this cellular immortality should not be attained by adult cells on which the finger prints of age and the sharp tooth of time have already left their mark, but embryonic cells may enjoy the same endless youth (if by that is meant unlimited power of propagation) as is shared by the immortal germ plasma.

The resemblance between a malignant tumor and a tissue culture such as has just been described is so evident that it does not need to be elaborated. The malignant tumor, like the embryonic tissue culture, toils

⁵ Evans H. M. Clinical Manifestations of Dysfunction of the Anterior Pituitary. *J. A. M. A.* 104: 464 (Feb. 9) 1935.

not, neither does it spin, so that its whole energy can be focused on reproduction. The malignant cells are affected by environment just as are the cells of a tissue culture. A carcinoma of the sigmoid may grow quite slowly, but the cells may grow with extreme rapidity when carried by the portal blood stream to the liver, and at autopsy the growth in the liver may completely overshadow the primary lesion. On the other hand, it may not. When blood-borne metastases occur in one organ, why should they not occur in every organ? In diffuse carcinomatosis the skeletal muscles must be deluged with tumor cells, and yet secondary growths are of the rarest occurrence. In a recent paper Oertel⁶ records a case of carcinoma of the stomach in which no metastases were evident at autopsy and yet all the organs in the body including the bones showed groups of tumor cells in the vessels. These cells had not succeeded in establishing a footing, in becoming colonized, the environment was unfriendly. Many years ago M. B. Schmidt demonstrated that metastatic groups of tumor cells could often be found in the pulmonary vessels surrounded by fibrin and dying for lack of nourishment. So that even the cancer cell has its weaknesses and is vulnerable, if only one knew how to attack it.

GROWTH OF CANCER CELLS

Cancer may be regarded in two ways. It may be the expression of a power for unlimited proliferation which develops in a tissue at a certain age, i. e., after the cells which compose it have gone through a certain number of mitoses. As this power is part and parcel of the very nature of the cell, it would seem that the cell was destined from the beginning to manifest this tendency when it had reached a certain stage of its genetic life history. As Lorrain Smith¹ puts it: "Cancer cells do not fall into the procession. They fall out. They do not keep step, the procession is moving slowly and they move fast." When identical twins develop at the same age in the same organ the same variety of malignant growth, as not infrequently happens, it would appear that the tendency toward malignancy formed part of the warp and woof of these cells.

On the other hand, a malignant condition can be imposed on cells from without by a number of agents known as carcinogenic, of which the most used in experimental work are coal tar and 1-2-5-6 dibenzanthracene. By means of external stimuli one can speed up the growth and division of cells whether in tissue culture or in the animal body. Of the exact mechanism by which this is accomplished, nothing is known, nor may it ever be known. It is extremely likely that the mechanism varies with different stimulating agents. Filtrable viruses, for instance, which have such a remarkable power to make epithelial cells multiply, penetrate directly into the interior of the cell. As a result of stimulation of the cells by such viruses definite benign papillomas may be formed, and the suspicion, long harbored in secret, is now being openly expressed that viruses may be responsible for true malignant tumors. McIntosh⁷ has shown that sarcomas may be produced in birds by tar injections, the same agent, it may be noted, that produces mammalian cancer, and that the majority of these tumors are transmissible by cell-free filtrates, strongly suggesting the presence of a filtrable virus. It is evident that, though

the tar plays the chief part in the induction of these tumors, it cannot be directly responsible for the subsequent malignant growths, as transmission to other animals is by means of a cell-free filtrate. The carcinogenic agent seems to play the role of a trigger mechanism, the subsequent stimulus being perhaps provided by a filtrable virus.

There is no reason why the two views of malignant neoplasia that have just been outlined should be mutually exclusive. It is reasonable to suppose that, if the innate tendency to neoplastic development is inherent in the cell, an extrinsic agency capable of speeding up the rate of cell division will bring the cell to that stage in its life cycle when this tendency is most likely to express itself. Champlin records the case of identical twins, one of whom died of a malignant tumor of the right testicle at the age of 31, the other was struck by a board on the right testicle at the age of 26 and shortly afterward a malignant tumor of that organ developed. In such an instance it would appear that the tempo of the process had been suddenly accelerated by an extrinsic factor.

The question may be asked, To what extent is it possible to modify conditions in the experimental animal so that the action of the carcinogenic agent may be modified? In answer to this question some experiments by Dr. J. R. Davidson⁸ of Winnipeg, although still in a preliminary stage, have yielded some interesting results. Davidson was struck by the fact that mice in which tar cancer develops resemble in many ways mice suffering from vitamin E deficiency. The apparent parallelism suggested that a deficiency of vitamin E and a carcinomatous condition induced by tarring produced general metabolic disturbances of comparable nature and that a diet unusually rich in vitamin E might inhibit the development of cancer. At the commencement of tarring the mice were transferred to a diet containing wheat germ cereal, wheat germ oil, and lettuce. In the last of Davidson's⁸ experiments, of nine mice on an ordinary diet all died of tar cancer, whereas of ten mice on a high vitamin E diet cancer did not develop in any. It would appear that a diet rich in vitamin E renders mice more resistant to the carcinogenic factor in tar than does a normal diet, but Davidson is careful to point out that such a diet is also rich in vitamins B and B₂. Whatever may be the precise factor concerned, this is apparently an example of the constitutional make up of an animal being so altered that it becomes resistant to the extrinsic carcinogenic agent.

CONCLUSION

In this brief review I have wandered far and wide, perhaps too far and too wide, but the peripatetic survey has revealed that growth is not only the most fundamental but also one of the most fascinating of problems, that it is controlled by a number of factors the disturbance of which may result in dwarfism, gigantism or deformity, that growth and differentiation are mutually inhibitory, that this inhibition may be overcome by removing cells from their environment and allowing them to grow in tissue culture, that cancer is the supreme example of freedom from restraint, and that something may be done in the way of imposing some degree of restraint from without.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER Secretary

DAVIS-BOVIE ELECTROSURGICAL UNIT ACCEPTABLE

Manufacturer The Liebel-Flarsheim Company, Cincinnati
This machine is recommended for electrosurgical cutting and coagulation. The firm states that the unit meets all electrosurgical requirements of transurethral prostatic resection, neurologic surgery, intrapleural pneumolysis or neoplastic, rectal, gynecologic and general surgery, and, in addition, special provisions have been made for the new high frequency method of treating detachments of the retina and for prostatic resection.

The electrical and mechanical characteristics of the unit compare favorably with the standards previously established by the Council for the acceptance of such apparatus.

An investigator who has had three years' experience with the unit reports that the device fulfils satisfactorily the purposes for which it is intended. When used for transurethral prostatic resection and electrosection of

bladder neck obstruction, the investigator finds that, while there is some bleeding, the coagulating current controls it, and that the cutting current cuts the tissue very well.

In view of the efficiency of the machine, the Council on Physical Therapy voted to include the Davis-Bovie Electrosurgical Unit in its list of accepted apparatus.

McINTOSH STANDARD DIATHERMY UNIT ACCEPTABLE

Manufacturer McIntosh Electrical Corporation, Chicago

The manufacturer recommends this unit for medical and surgical diathermy. It is a portable diathermy machine, of the usual construction for a small unit, enclosed in a leatherette case. The main line switch is mounted on the panel. The binding posts for the treatment cords are mounted on the front of the panel and a four gap spark gap covered by a metal screen is mounted on top of the panel. It has a four point voltage selector switch (rheostat) and a typical milliamperemeter protected by fuses, with two scales 0 to 1,000 and 0 to 4,000. The unit weighs about 55 pounds. This machine is supplied also in a floor cabinet of modernistic design.

At the request of the Council the manufacturer submitted data containing a report of tests of the unit for power input and output and for its spark gap and transformer temperature rise. The results recorded in the data were in agreement with the observations of the Council's investigator and in conformity with the standards for diathermy machines previously established by the Council.

Fig 1—McIntosh Standard Diathermy unit

From a clinical standpoint, the Council's investigator reported that the machine gave satisfactory performance for the purposes for which it is recommended.

Fig 2—Schematic diagram of circuit

In view of the foregoing report, the Council voted to include the McIntosh Standard Diathermy Unit in its list of accepted apparatus.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

OLAV'S A AND D VITAMIN PÂTÉ

Manufacturer—Thor Cannery, Fredrikstad, Norway

Description—Canned cooked mixture of ground cod livers, potatoes, eggs, salt, mace, nutmeg and white pepper.

Manufacture—Fresh cod livers on receipt at the cannery are inspected for soundness, washed, trimmed, mechanically ground and thoroughly mixed with formula proportions of steam cooked potatoes, eggs, salt and spices. The mixture is packed by hand in cans which are sealed and processed under 5 pounds pressure for from one to one and one-quarter hours. The product is packed only during January, February and March.

Analysis (submitted by manufacturer)—

| | per cent |
|--|----------|
| Moisture | 54.2 |
| Ash | 0.8 |
| Fat (ether extract) | 28.1 |
| Protein (N x 6.25) | 4.7 |
| Crude fiber | 0.3 |
| Carbohydrates other than crude fiber (by difference) | 11.9 |

Calories—3.2 per gram 91 per ounce

Vitamins—Vitamin assay shows 5,000 U. S. P. units of vitamin A and 1,000 U. S. P. units of vitamin D per ounce.

Claims of Manufacturer—An appetizing spread for conveniently providing children and adults with vitamins A and D of cod liver oil. One level teaspoonful is equal to one half teaspoonful of U. S. P. standard cod liver oil in vitamin A and three fourths teaspoonful in vitamin D.

(1) VALLEY BREAD

(2) VALLEY ROYAL LOAF

Manufacturer—Valley Baking Company Inc., Shippensburg, Pa.

Description—White breads made by the sponge dough method described in THE JOURNAL, March 5, 1932, page 817. (1) prepared from flour, water, condensed skimmed milk (sweetened), sugar, lard, salt, yeast, butter, malt extract and a yeast food containing calcium sulphate, sodium chloride, ammonium chloride and potassium bromate. (2) prepared from flour, water, condensed skimmed milk (sweetened), lard, sugar, salt, yeast, malt extract, honey and a yeast food containing calcium sulphate, sodium chloride, ammonium chloride and potassium bromate.

THE POLIOCIDAL SUBSTANCE IN HUMAN SERUM

As man matures he acquires more resistance to some of the infectious diseases. The adult is not often the victim of measles, pertussis and poliomyelitis. Difficulty has been experienced in explaining the fact that the serum of a majority of normal adults will inactivate the virus of poliomyelitis in vitro. Many of these adults are without a history of an attack of infantile paralysis, and even exposure to the antigen apparently can be ruled out in many others, nevertheless the immunologic effects of their serums are indistinguishable from those brought about by the specific antibody. What is the origin of the normal poliocidal substance in these serums? There are several possibilities. It may arise as the consequence of an infection with the etiologic agent of the disease which does not become manifest, some other common infection may cause its production, and, finally, these neutralizing substances may be only the result of normal physiologic changes in the maturing organism.¹ Jungeblut and his associates have reported a variety of interesting experimental observations. They performed virucidal tests with pooled lots of serum from adults of the same blood group who gave a history of an attack of paralysis, and also on another group whose serum was normal. The virucidal titer of adult normal serum from blood group A individuals was found to lie between 1/5 and 1/25, that of serum from the blood group O individuals between 1/25 and 1/40, and that of serum from normal blood B individuals between 1/40 and 1/80. The titer of adult convalescent serum of blood group A was between 1/15 and 1/20, of blood group O serum between 1/10 and 1/20, and of blood group B serum between 1/60 and 1/80. These data suggest that the titer of convalescent serums in blood group O may be considerably below that of normal serums while no fundamental difference exists in blood groups A and B in the neutralizing capacity of the two kinds of serum. In testing the thermostability of the pooled

serum, they found that convalescent serum from blood group O individuals was more thermostable than normal serum from blood group O, a significant difference in this respect was not detected between the normal and convalescent serums from blood groups A and B. The thermostability of the serum depended largely on the amount of antibodies present. It appears, therefore, that the normal poliocidal substances in human serums are in quantity and in resistance to heat equal to and in some cases superior to the poliocidal substances that develop as the result of convalescence from poliomyelitis.

The specificity of the neutralization of poliomyelitis virus by serum was investigated. A number of antitoxic, antiviral and antibacterial serums were tested for their capacity to inactivate poliomyelitis virus. Perhaps the most interesting result of these experiments was the high percentage of positive tests obtained with diphtheria serums. The investigation was carried further by testing for virucidal power the serum of fifteen monkeys that had been immunized with various preparations of diphtheria toxin and toxin antitoxin. Also the resistance of these animals to intracerebral inoculation with small doses of poliomyelitis virus was determined. Two of the monkeys completely resisted the intracerebral infection and five others developed only light symptoms of infection. Eight of the monkeys succumbed to poliomyelitis. The immune serums of three of the protected monkeys had definite virucidal power. Schick tests were then made on fifty normal monkeys and, for comparison, also on fifty different monkeys that were convalescent from poliomyelitis. It was found that a great majority of the monkeys convalescent from poliomyelitis gave a negative Schick test. This peculiar relation between an increase in tolerance for diphtheria toxin and insusceptibility to poliomyelitis virus in monkeys was followed by a study on man to see whether any parallel could be demonstrated between the results of the Schick test and the presence or absence in the serum of virucidal substance against poliomyelitis virus. The result was that the two reactions agreed in the majority of cases. The exceptions, however, were frequent.

While these experiments invite further research, they seem to show that no fundamental differences exist in the quantities of virucidal substance in adult normal or adult convalescent human serum, with the exception of convalescent serums from blood group O, which show consistently low virucidal titers. High titered serums were found to be more thermostable than low titered serums, irrespective of the source of the serum.

The most important observation, however, was not only that poliomyelitis virus can be inactivated by an antibody in the serum formed as the result of contact with the specific antigen but also that, during immunization with certain bacterial and animal toxins, substances may arise in the serum which will inactivate the virus. This substance is not as yet known. The

¹ Jungeblut, C. W. The Immunological Characteristics of the Poliocidal Substance in Human Serum. *J. Immunol.* 27: 17 (July) 1934.

authors believe that it is not the recognized antitoxin but a by-product of the immunization. It is conceivable, they say, that diphtheria toxin, for example, when introduced parenterally in small doses stimulates the endocrine system, releasing certain principles into the circulation and tissues. In fact, in another paper Jungeblut and his associates² report experiments in which poliomyelitis virus was inactivated in vitro by certain biologic products containing the anterior pituitary-like gonadotropic principle of pregnancy urine and by epinephrine. They also showed that diphtheria toxin was inactivated in vitro by pregnancy urine preparation and by adrenal cortex extract. Ultimately, they believe, it may be shown that susceptibility to both diphtheria and poliomyelitis is the result of some endocrine deficiency and that protection against one of these two diseases may be associated with some resistance against the other. At present this hypothesis is difficult to verify.

INDUSTRIAL DERMATOSES

Industrial dermatoses constitute approximately 60 per cent of the industrial diseases not including actual accidents, they are, thus, of considerable medical and legal importance. Eller and Schwartz¹ have recently reported a study of the cause, prevention and treatment of such skin disturbances. While the matter of predisposition is still uncertain, blondes, the relatively young and the aged are perhaps more susceptible than others to skin irritants. Certainly diseased and abnormal skins are more susceptible than thick and oily ones. Poisoning by heavy metals may possibly act as a predisposing agency. The chief causes of industrial dermatitis differ in various localities, according to the prevailing types of industry, but it can be safely stated that in general the majority of industrial skin diseases in the United States are caused by the action of acids, alkalis, caustics, oils, greases, solvents and plants. It is possible, the authors believe, to classify the cases in a simple way into physical agents, general irritants such as acids, strong alkalis and caustics, specific irritants that do not affect every one but do irritate a considerable percentage, many plants such as ivy and oak, and biologic agents such as parasites, bacteria and fungi.

When the average patient is first affected with itching and burning and the visible signs of an occupational dermatitis, his clinical appearance on examination, excepting in a few cases, does not offer a clue to the nature of the irritant. The differential diagnosis from skin diseases due to other causes may, in fact, be most difficult. There is nothing in the appearance of industrial dermatitis to differentiate it from similar contact eczemas caused by noxae in the patient's home or elsewhere. The patch test may be of diagnostic importance in determining the source but is not absolutely depend-

able. False positives may be obtained with benign substances due to accompanying impurities. Contrariwise, the patch test may be negative because it does not represent or simulate actual working conditions. Thus friction may be the missing factor. Sometimes heat or ultraviolet radiation must coexist.

A person who is sensitive to the material with which he works and cannot develop an immunity or "become hardened" to it should seek some other occupation. If uncomplicated, the dermatitis should disappear when a worker is away from the substance that has caused it. Most cases of industrial dermatitis develop in new employees or those exposed to a new irritant and are usually mild in character. Sometimes mild protective ointments will aid in the establishment of "immunity" and allow continued working. In certain cases, desensitization has been successfully employed.

Prevention should be the primary aim. The ideal method is to safeguard the industries which have skin hazards so that the injurious chemicals will not come in contact with the skin of the worker. Protective ointments have also been found useful pending more suitable preventive measures. The laws regarding compensation for industrial skin diseases are not uniform in different states. It would do much to clarify the situation if model laws for compensation could be drafted and enacted in a uniform manner throughout the states. At present it is advisable for the physician handling such cases to become familiar with the compensation law of his own state.

BASAL METABOLISM AND IODINE EXCRETION DURING PREGNANCY

Pregnancy is accompanied by a progressive increase in the basal oxygen consumption. There is, moreover, a considerable amount of evidence tending to support the view that the thyroid is involved in the metabolic reaction of the normal woman to pregnancy. A group of Ohio State investigators¹ have recently reported a study of the factors affecting the increase in metabolism occurring in pregnancy, the urinary iodine excretion and the effects of advancing pregnancy on vital capacity and tidal air.

Eight subjects were used in these studies. Seven were primiparas ranging in age from 15 to 20 years, who were inmates of a home for unmarried mothers and therefore had uniform dietary and sleeping habits. All were normal cases of pregnancy terminating in uncomplicated labor and healthy infants. None of them showed any symptoms of thyroid dysfunction.

All determinations of basal metabolism were made by means of the closed circuit type of apparatus generally known as the Benedict-Roth. With four of the women a study was made of the iodine excreted in the

urine Twenty-four hour samples of urine were collected by each of the subjects each week The total quantity of iodine contained in the samples was determined by means of the Phillips and Curtis modification of the Fellenberg method

Five of the seven inmates of the institution were given iodized salt Inspection of the metabolism studies showed that in every case there was an increase in the metabolic rate toward the end of pregnancy This increase was, however, of greater magnitude in the younger subjects The two who did not receive iodized salt were under observation only during the last month of pregnancy The rise in metabolism of one of these as well as the drop that occurred at parturition was of greater magnitude than was obtained with any of the women who received iodized salt From an inspection of the curves of body weight and basal oxygen consumption it was apparent that in all but one of the seven there was a close correspondence between changes in body weight and variations in oxygen consumption This fact naturally suggests that the energy required in laying down the new tissue of the fetus and accessory structures is an important factor in producing the increased heat production of pregnancy It was noteworthy also that with adolescent girls there seems to be another stimulating factor at work, which results in a more marked rise in the metabolism of such subjects than that which occurs during the pregnancy of more mature women

The results obtained in the study of urinary iodine excretion carried out on four patients throws further light on the relation of the iodine of the diet to the metabolism of pregnancy Those who were using iodized salt excreted from three to ten times as much iodine as did the one who received no supplementary iodine. This may be taken as probable proof that iodized salt added to an ordinary diet furnishes an adequate supply during pregnancy There is, however, no apparent relationship between iodine excretion and the magnitude of the increase in metabolism as pregnancy advances The principal feature of these results was the marked increase in the urinary iodine excretion that occurred in the third week ante partum in three of the patients who were receiving iodized salt The meaning of this is not clear, but it must indicate a profound modification of iodine metabolism and possibly it accompanies a change in thyroid function

Finally the changes that occur in vital capacity and tidal air during pregnancy were studied on seven patients In all but one there was a definite increase in vital capacity as pregnancy advanced, although in two of the six there was a drop in the last week With four the vital capacity decreased after parturition and with one there was a gradual decrease in vital capacity during the last three months of pregnancy, which was followed by marked improvement after delivery In six of the seven patients, therefore, the increase in

abdominal contents was associated with an increase rather than a decrease in vital capacity Furthermore, it seems that the increased oxygen consumption of pregnancy is accomplished by an increase in the volume of tidal air

Current Comment

MILK FOLLY

The state of New York is taking its milk industry seriously! In fact, it seems to be taking it so seriously that the advertising agencies are making it ridiculous Apparently they have found it necessary to sell milk as a medicine rather than as the wholesome food it really is These remarks are prompted by the appearance in New York newspapers of a new type of advertisement in which the value of milk as a cure for several complaints is emphasized Strangely enough, the emphasis is also untrue The complete text of the advertisement reads

ALKALIZE WITH MILK! At one time or another you certainly have felt the need of alkalizing But chances are that you didn't take milk because you didn't realize that milk is a natural alkaliizer fresh, cold milk

Milk—the alkaliizer—works like a charm Over indulgence, after noon fag any time that acid products accumulate in your blood, simply alkalize with milk. Every glass of milk has a definite alkaline effect And there's real economy in using milk one of today's best food buys

Free Booklet—Milk—the Alkaliizer Write to The Bureau of Milk Publicity Albany

THE STATE OF NEW YORK

The Bureau of Milk Publicity of the New York State Department of Agriculture and Markets also issues a folder in which these facts are reemphasized, reiterated and even more exaggerated It is amusing to realize that directly opposite this advertisement appears one for a "patent medicine" with exactly similar claims It should be unnecessary to point out for a medical audience that milk is the only article of diet whose sole function in nature is to serve as a food Certainly the values of milk in protein, in mineral salts and in vitamins are sufficient on which to base claims as to its usefulness without trying to turn the product into a "patent medicine" Officials in the state of New York will do well to select an advertising agent more conversant with the facts of medical science and nutrition

SELF DETERMINATIONS OF BLOOD PRESSURE

Here and there in amusement parks throughout the country all sorts of peculiar devices are being exploited in relationship to determinations by individuals of their own physiologic functions For years men have been especially interested in having the records of their weights and heights Then came devices of the spirometer type, whereby lung capacity could be determined, and also the ergometer for measuring the strength of the hand or the force of a blow with a fist There are also machines for measuring the pulling power of man as well as of horses and of mules More recently devices have appeared which presume to give information regarding the heart beat The latest wrinkle is the

adaptation of mechanical devices for measuring the blood pressure. The manufacturers of such apparatus, including those of the mercury manometer and of the spring type, protest earnestly and long that they are doing their utmost to stop the sale of such devices to persons outside the profession. Certainly there is great danger to the public inherent in the employment of such apparatus without the necessary medical background for interpreting the results of the investigation. Any single reading of blood pressure, pulse rate or even temperature, without relationship to the general physical condition and mental condition of the person concerned, is bound to lead to false interpretations and the associated hypochondria.

ACTIVE IMMUNIZATION IN POLIOMYELITIS

Investigators have learned during many years of experimentation that the virus of poliomyelitis is strikingly unstable in its disease-producing properties. Specimens of virus of high virulence may suddenly decrease in activity and then after a time regain the lost power while being preserved in glycerin. On the other hand, some strains of poliomyelitis virus show weak activity and frequently fail to induce infection in the monkey. As early as 1910, Flexner and Lewis¹ discovered that in the process of immunizing *Macacus* monkeys with living virus a proportion of monkeys instead of becoming immune always became paralyzed. Numerous attempts have been made to modify poliomyelitis virus so as to preserve its immunizing properties and at the same time to remove its paralyzing action. Flexner² has recently stated that, while both physical and chemical means have been employed for this purpose, the results have not been satisfactory. Whenever the modifying agents inactivated the poliomyelitis virus, immunity failed to follow the inoculations, and when such modifying agents reduced the activity, immunity would result but paralysis would result also. In other words, the effect of the modifying agents seems to be a dilution of the virus and not an attenuation. The virus recovered from paralyzed monkeys that had been infected with the chemically treated virus resembled in virulence the original virus strain before the treatment was begun. When the human virus is injected into the skin of *Macacus* monkeys it produces active immunity in most of them but produces paralysis in some of the inoculated animals just as the passage strains of virus do. In view of experimental studies made during the 1931 epidemic in New York and of various other studies, Flexner believes that there is no evidence showing that the passage of virus through monkeys removes its power to infect and produce paralysis in man. There are, on the contrary, he says, convincing observations which show that an indeterminate number of passages of virus through human beings does not deprive the virus of its potential paralyzing effect when injected into monkeys. The available evidence also indicates that poliomyelitis

virus which has been exposed to injurious physical and chemical agents is either destroyed or merely reduced in concentration. When therefore the virus has been destroyed by the physical or chemical agent it no longer has immunizing power, and when it has only been reduced in concentration by the modifying agent it immunizes certain animals and may paralyze others. The fact that fully active virus has been recovered from the paralyzed animals proves, it is said, that the treated active virus has not been attenuated.

AN UNUSUAL PUBLIC EDUCATION SERIES

The New York Academy of Medicine, realizing the great development of interest on the part of the public in the advances that are taking place in medical science, has outlined an extraordinary group of lectures for the public, which began in the Academy of Medicine on October 3. The series that has been developed is entitled "Art and Romance of Medicine" and the lectures together with the dates on which they are to be given follow:

Wisdom of the Body, by Walter B. Cannon, M.D., professor of physiology, Harvard Medical School, October 3

Medicine in the Days of the Great Monarch, by Howard W. Haggard, M.D., associate professor of applied physiology, Yale University, November 14

The Mystery of Death, by Alexis Carrel, M.D., Rockefeller Institute for Medical Research, December 12

Medicine of the American Indian, by Harlow Brooks, M.D., emeritus professor of clinical medicine, New York University, Jan. 9, 1936

How We Learned About the Human Body, by Benjamin P. Watson, M.D., professor of obstetrics and gynecology, Columbia University, February 13

The Organic Background of Mind, by Foster Kennedy, M.D., professor of neurology, Cornell University Medical College, March 12

The Story of Vitamins, by Elmer V. McCollum, M.D., School of Hygiene and Public Health, Johns Hopkins University, April 9

Man—The Common Denominator of Disease, by George Draper, M.D., associate professor of clinical medicine, Columbia University, May 14

It will be interesting to learn how far public interest will go in attending these lectures and whether or not the attendance gradually increases with each successive engagement. Such interest as is bound to be displayed by this series will be reflected in the sympathetic understanding of medical problems, which is so necessary for developing the future of medicine in this country.

RADIO BROADCASTS

The American Medical Association broadcasts over the Blue network and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers a toast "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The next three programs are as follows

November 12 Infection, Morris Fishbein M.D.
November 19 Common Household Emergencies W. W. Bauer M.D.
November 26 Automobile Accidents, Morris Fishbein M.D.

This program is broadcast also on the short waves through KDKA, Pittsburgh, over station W8XK, 11,870 and 12,210 kilocycles.

Debate on State Medicine

November 12, at 2 o'clock eastern time a trial debate is to be held over the network of the National Broadcasting Company on the subject 'Resolved, That the several states should enact the legislation providing for a system of complete medical service available to all citizens at public expense.' The speakers for the affirmative are William T. Foster and Bower A. J. The speakers for the negative are Dr. R. G. Leland, director of the Bureau of Medical Economics of the American Medical Association, and Dr. Morris Fishbein, editor of THE JOURNAL.

The speakers at the evening meeting were Drs. Charles O. Giese and Ardan M. Mullett, Colorado Springs. At a meeting of the Fremont County Medical Society in Canon City recently, Dr. Raynor E. Holmes Jr. read a paper on 'Differential Diagnosis and Treatment of Peptic Ulcer'. A symposium team

representing the committee on tuberculosis education of the state medical society presented the program before the Northeast Colorado Medical Society in Sterling recently, speakers were Drs. William Wiley Jones, Charles J. Kaufman and John S. Bouslog, Denver. The Pueblo County Medical Society was addressed recently by Dr. Dwight B. Shaw, Pueblo, on 'Effects of Disease on History' and, September 17, by Dr. Lawrence E. Berg, Boone, 'Childbirth'. Members of St. Joseph's Hospital staff presented the program before the Medical Society of the City and County of Denver, October 15. Drs. Albert W. Metcalf, 'Peripheral Arterial Diseases, Diagnosis and Treatment', Glen E. Cheley and Leonard Freeman Jr., 'Unusual Case of Ectopic Pregnancy', Duval Prey, 'Imperforate Anus' and Philip Work and Chesmore Eastlake, 'Encephalitis in Chickenpox'. Speakers before the Boulder County Medical Society, October 10, in Boulder, included Drs. Warren M. Gilbert and Walter K. Reed on action and uses of irradiated petrolatum.

Hobby Display at State Meeting—The Colorado State Medical Society, for the first time, featured an exhibit of the hobbies of its members during the recent annual meeting. The hobbies were interspersed with the scientific exhibits, instead of being arranged as a special exhibit. The group included

Photographic compositions, Drs. Cuthbert Powell and William H. Crisp, Denver.
Stamp collections, Drs. Philip Work and Anders J. O. Lof, Denver.
Entomology, Dr. Tracy R. Love, Denver.
Tinted miniature photographs on ivory, Dr. Nolie Mamey, Denver.
Ship model, Dr. Douglas W. Macomber, Denver.
Ink sketches, Dr. Crisp.
Collection of paintings, Dr. Gerrit Heusinkveld, Denver.
Western Americana, Dr. Harry S. Finney, Denver.
Water color sketches, Dr. Chesmore Eastlake, Denver.
Collection of chiropractic advertisements, Dr. Duane Turner, Steamboat Springs.

It is hoped to make the display of hobbies an annual feature of the state meeting.

CONNECTICUT

In Commemoration of Dr. Peter Parker—The one hundredth anniversary of the establishment of the Ophthalmic Hospital in Canton, China, by Dr. Peter Parker, who introduced modern medicine in China, was observed by Yale University, November 5. Mr. Tsune-chi Yu, Chinese consul general at New York, representing Ambassador Sze, was among the speakers. Dr. Samuel C. Harvey, William H. Carmalt, professor of surgery at Yale, spoke on 'Peter Parker, Initiator of Modern Medicine in China', and Rev. Kenneth S. Latourette, D. Willis James, professor of mission and oriental history, Yale Divinity School, gave an address on 'Peter Parker, Missionary and Diplomat'. There was an exhibition of paintings by the Chinese artist Lamqua illustrating the work of Dr. Parker, his portraits and memorabilia which he presented to the Yale University School of Medicine. November 4 a celebration commemorating the same event was held in Canton. Dr. Edward H. Hume, president of Yale-in-China, presented a portrait of Dr. Parker, with greetings to the Canton Hospital. Dr. Parker graduated from the Yale school of medicine and the divinity school in 1834. He was the first Protestant medical missionary to enter China. In 1835 he, with the assistance of British and American merchants, opened the Ophthalmic Hospital. He specialized on diseases of the eye, particularly on the removal of cataracts. In 1838, largely through his influence, the Medical Missionary Society was formed in China. He returned to the United States in 1840 on account of war between Great Britain and China but returned to China in 1842. In 1844 he served as secretary to Caleb Cushing, negotiating the first treaty between the United States and China. In 1845 he was appointed secretary to the American legation, and in intervals between commissions was chargé d'affaires, continuing at the same time his medical practice. In 1855 he became American commissioner and minister to China, remaining in China until 1857. He died in Washington in 1888, at the age of 84.

DISTRICT OF COLUMBIA

Personal—Dr. Daniel L. Seckinger, formerly epidemiologist for the Georgia State Department of Health, has been appointed assistant health officer for the District of Columbia. Major Gen. Charles R. Reynolds, surgeon general of the U. S. Army, was guest of honor at a reception given by the Medical Club of Philadelphia, October 18. Surgeon General and Mrs. Reynolds were guests at a reception recently given by medical department officers of Washington and vicinity.

Monthly Army Meetings—The monthly meetings of the officers of the medical department of the U. S. Army living in Washington and vicinity were resumed, October 21, when Major Gen. Charles R. Reynolds, surgeon general of the army, discussed the activities and policies of the medical department.

These meetings will be held on the third Monday of each month at the Medical Center and will continue until May. Commissioned officers (active, reserve and retired) and physicians of the medical services of the army, navy, public health service and veterans' administration, and members of the medical and dental professions of the District of Columbia are invited.

ILLINOIS

Eighteen Thousand New Cases of Syphilis—The Illinois State Department of Health announces that venereal diseases are now by a wide margin the greatest of all health hazards to young adults. About 18,000 new cases of syphilis are reported annually in the state, already more than 14,000 cases have been reported this year. Nearly two thirds of the 225,000 diagnostic laboratory tests made annually by the state department of public health relate to syphilis. The department spends \$20,000 annually for drugs for the treatment of indigent patients alone. About 1,400 mental patients are always in state hospitals at an annual cost of about \$500,000 because of syphilis. More cases of the disease are reported than of any other disease except measles and scarlet fever, the department reports.

Chicago

Society News—Speakers before the Chicago Gynecological Society, November 15, will include Drs. Fred O. Priest, Chicago, and Gilbert P. Pond, Oak Park, on 'Surgical Complications of Pregnancy' and 'Positive and Permanent Identification of the New-Born' respectively. Dr. Ruth R. Darrow discussed 'Icterus Gravis in the New-Born' before the Chicago Council of Medical Women, November 1. At a meeting of the Chicago Laryngological and Otological Society, November 4, Drs. Alfred Lewy read a paper on 'After Care of the Radical Mastoid Operation', Samuel Salinger, Rhinoplasty, 'Some Practical Considerations,' and Richard L. Webb, Ph.D., 'Lymphatics of the Head and Neck.'

Free Medical Service Analyzed—The council of the Chicago Medical Society unanimously adopted a report of a study of the abuse of free medical service in outpatient practice at a meeting, October 9. In the six teaching outpatient departments studied, which handle about 60 per cent of the free outpatient work in Chicago, the service was found to be abused to the extent of 13 per cent, ranging from 22 per cent in one institution to 6 per cent in another. Of the 5,615 consecutive admissions reviewed, 1,484, or 26.4 per cent were found to be appropriate for home visits for investigation, 300, or 5.3 per cent, were not suitable for home visits because the patients were nonresidents of Chicago and for various other reasons. 478, or 8.6 per cent, were excluded because the question of abuse did not enter into the matter, and 3,353, or 59.7 per cent, were cases receiving relief when admitted. This last group of cases was not included in the study, since it was assumed that sufficient investigation had already been made and these persons were entitled to free care. Complete information was obtained on 1,043, or 70 per cent of the 1,484 cases suitable for home visits. In this group it was found that 66.1 per cent had incomes of less than \$1,000 each year and 90.8 per cent received less than \$1,500. The survey was conducted by Dr. William H. Walsh, hospital consultant, for the committee on medical economics of the Chicago Medical Society to determine the extent of abuse of free medical service by those able to pay private physicians and to ascertain the standards used in establishing the economic eligibility of patients accepted for free care. The institutions studied were Central Free Dispensary, Children's Memorial Hospital Dispensary, Mandel Clinic of Michael Reese Hospital, Mercy Hospital Free Dispensary, Northwestern University Medical Clinics and the Research and Educational Hospital of the University of Illinois. The two institutions with the lowest percentages of abuse are those in which the social service divisions are best administered and staffed. The report recommends (1) that the standards for admission administration and medical service be improved, (2) that the medical profession take steps to apprise the public of the fact that private medical service is available at a price within the reach of the patient of moderate means, and (3) that there be organized a standing committee or council on hospitals and clinics to represent the society in all matters concerned with these institutions.

INDIANA

Society News—The Hamilton County Medical Society was addressed in Arcadia, October 8, by Dr. Matthew Winters, Indianapolis, on 'Scarlet Fever and Nephritis.' At a meeting of the St. Joseph County Medical Society in South Bend, October 1, Dr. Joshua M. Gordon, South Bend, discussed rheumatic heart disease. A symposium on toxemia of late pregnancy was presented before the Indianapolis Medical

Society, October 29, by Drs. Gerald W. Gustafson, Henry F. Beckman and John E. Dalton, all of Indianapolis. Dr. Clifford G. Grulee, Evanston, Ill., will discuss 'Anemias of Infancy' before the Tippecanoe County Medical Society, November 12.

LOUISIANA

Society News—At a meeting of the St. Tammany Parish Medical Society, recently, speakers were Drs. Manuel M. Garcia, New Orleans, on the role of the general practitioner in cancer control, and Daniel N. Silverman, New Orleans, on bacillary and amebic dysentery. A symposium on pain in the lower part of the back was presented before the Orleans Parish Medical Society, October 14, by Drs. John F. Dicks, John G. Pratt and George C. Battalora, New Orleans. Dr. Jacob M. Bodenheimer discussed the incidence and diagnosis of ectopic pregnancy before the Shreveport Medical Society recently. Dr. Oscar W. Betha, New Orleans, conducted a clinic on cardiac diseases before the Fourth District Medical Society, October 1, and Dr. William R. Mathews, Shreveport, discussed a case of lipid pneumonia of the right lung with secondary pneumococcal endocarditis, terminating in a fatal pulmonary infarction of the left lung.

MARYLAND

Society News—At a meeting of the Baltimore City Medical Society, November 1, speakers included Drs. Ernest H. Gaither on 'Therapy of Peptic Ulcer,' Conservative versus Radical, Paul Padgett and Joseph E. Moore, 'Interrelationships of Tuberculosis, Syphilis and Antisyphilitic Treatment,' and Charles M. Byrnes, 'Treatment of the Postherpetic Neuralgias.' At a meeting of the Maryland Academy of Medicine in Baltimore, October 14, Dr. Thomas P. Sprunt, among others, discussed endocrine neoplasms. Dr. Charles Loring Joslin addressed the Baltimore County Medical Association in Baltimore, October 16, on 'Causes of Malnutrition in Infants.'

Malnutrition Decreases—A decrease in the percentage of children showing signs of malnutrition and an increase in the percentage of defects corrected are indicated in the report of the medical examination of children in the public and parochial schools in Baltimore County during the school year ended July 31 according to the state department of health. Children who were 10 per cent or more underweight or who gave other evidence of malnutrition comprised 13.6 per cent of the total number examined, as compared with 16.9 during 1933-1934, 14.6 in 1932-1933 and 16.2 in 1931-1932. The percentage of corrections completed during the year of 1934-1935 was 40.3 as compared with 32.9 in 1933-1934, 22 per cent in 1932-1933 and 12 per cent in 1931-1932.

MASSACHUSETTS

The Gay Lecture on Medical Ethics—Dr. James B. Herrick, professor emeritus of medicine, Rush Medical College, Chicago, delivered the George W. Gay Lecture on 'Medical Ethics' at Harvard Medical School, November 7. His subject was 'The Care of the Patient.' Lectures will be given by Dr. Arthur R. Crandell, Taunton, November 14, and by Dr. David D. Scannell, Boston, November 21.

Society News—Dr. Reginald Fitz, Boston, discussed 'Recent Advances in Medicine' before the Hampden District Medical Society in Springfield, October 29. A symposium on silicosis and asbestosis was presented before the Massachusetts Society of Examining Physicians in Boston, October 30. Speakers before the Norfolk District Medical Society in Sharon, October 29, were Drs. Walter A. Griffin, Sharon, and Edward D. Churchill, Boston, on 'Early Diagnosis of Tuberculosis and Treatment of Bronchiectasis' respectively.

MICHIGAN

New Executive Secretary of State Society—William J. Burns, Detroit, executive secretary of the Wayne County Medical Society since 1930, has been named to a similar position with the Michigan State Medical Society, effective November 1. Mr. Burns may be addressed at suite 2020 Olds Tower, Lansing. Dr. Clifford T. Ekelund, Pontiac, will be secretary of the society succeeding Dr. Burton R. Corbus, Grand Rapids, who has been acting secretary. Mr. Burns, who has a degree of bachelor of laws from St. John's College, Toledo, before becoming associated with the Wayne County Medical Society, was executive secretary of the Academy of Medicine of Toledo and Lucas County, Ohio.

Personal—Dr. Romulus S. Buckland, Baraga, was honored October 19 when a new recreation field in the township was dedicated in his honor. Dr. Buckland is 69 years of age and has been practicing in the community for thirty five years.

MISSOURI

Society News—Dr John C Morfit discussed "The Opportunity and Responsibility of Organized Medicine in Relation to Economic Trends" before the St. Louis Medical Society, October 29, the program was under the auspices of the section on medical economics of the society.—The South Central Counties Medical Society was addressed in Houston, recently, by Drs Adolph H Conrad, on "Common Drug Eruptions", Richard S Weiss, "Precancerous Skin Lesions," and Martin F Engman Jr, St. Louis, "Contact Dermatitis."

Cancer Clinic at State Hospital—A fully equipped cancer clinic will be constructed at the state hospital at Fulton, as a part of a \$1,500,000 building program for state hospitals. The clinic will be located in a penthouse on the new building to be erected and, in the beginning, will accommodate twenty-four patients. Definite plans for the clinic were discussed at a recent meeting in St. Louis, which was attended by representatives of the eleemosynary board, the committee on cancer of the state medical association and members of the staffs of the state hospitals. Through an act of the last legislature, indigent persons suffering from certain conditions other than mental diseases may now be treated in the eleemosynary institutions.

MONTANA

Dr Kilbourne Named State Epidemiologist—Dr Burton K Kilbourne, health officer of Fargo, N. D., since 1923, has been appointed epidemiologist to the Montana State Board of Health at Helena, effective October 1. Dr Kilbourne was a graduate of Kansas Medical College, Topeka, in 1904.

NEBRASKA

Fall Clinic—St. Elizabeth's Hospital, Lincoln, held its annual fall clinic, October 11-12. The following speakers were guests of the hospital: Drs Harold Swanberg, Quincy, Ill., Roland M Klemme, St. Louis, Kellogg Speed, Ralph C. Brown and Wilber E. Post, Chicago, and Mr C. E. Lounsbury, Chicago, former assistant state's attorney of Illinois.

NEW JERSEY

Society News—A symposium on ulcerative colitis was presented before the New Jersey Gastro Enterological Society in Newark, November 4, by Drs Asher Winkelstein, Joseph Felsen and Thomas T. Mackie, all of New York.—The Society of Surgeons of New Jersey will meet at Atlantic City, January 15.

NEW MEXICO

Personal—Dr Sophie B. D. Aberle, recently of New Haven, Conn., has been appointed in charge of the Pueblo Indians in the vicinity of Albuquerque. Dr Aberle was graduated from Yale University School of Medicine in 1930 and has been engaged in research there and in Baltimore.—Dr Frank C. Diver, Springer, has been appointed health officer for the ninth New Mexico health district.

NEW YORK

Medical Society Conducts Immunization Campaign—The Medical Society of the County of Albany recently reported that a diphtheria immunization campaign carried out in 1934 in the manner of the "Detroit plan" resulted in an increase of the proportion of immunized children from 32 to 54 per cent. Features of the plan, which was worked out in cooperation with the city departments of health and education, were that physicians set aside hours during which they would give the treatments at a fee of \$1, that the health and education departments agreed not to hold clinics and that the health department would reimburse the physicians for their immunization of indigent children.

County Society Plan for Medical Care—The Medical Society of the County of Nassau announces the establishment of a Charity Public Health and Medical Hour to provide medical care, both preventive and curative, to persons unable to pay the regular charges for service. To protect the physicians from imposition, it has been decided to restrict the service to patients referred by public health or school nurses. Most of the members of the society have arranged to set aside special office hours each week during which they will render any type of care that can be given in an office at a fee of \$1 per visit. In addition to advice and treatment for those who are sick, they will also offer immunization against diphtheria, vaccination against smallpox, examination of apparently well babies or preschool children, care of women during pregnancy, and eye examinations. If the patient is unable to pay even the reduced fee the nurse who refers him is requested

to notify the physician, and the services will be given without charge. In the case of persons on the relief rolls, the regular medical authorization from the relief bureau must be obtained. Welfare departments do not pay for the preventive services, but if persons on the welfare list desire them and are unable to pay the dollar fee, they will be treated without charge if they bring a note from the nurse explaining the circumstances.

Society News—An institute on conservation of vision arranged by the bureau of prevention of blindness of the state department of social welfare was held in Rochester, October 15-16. Among speakers were Drs Eugene R. Vernou, on "Metabolism and Nutrition in Relation to the Eyes", Harry S. Gradle, Chicago, "Prevention of Blindness," and Louis Resnick, director of industrial relations, National Society for the Prevention of Blindness, "Eye Accident Hazards at Work and at Play"—Dr Josephine B. Neal, New York, addressed the Mount Vernon Medical Society October 10, on "Diagnosis and Treatment of Acute Anterior Poliomyelitis"—Drs Cornelius Mezei, Comstock, and Edwin MacDonald Stanton Schenectady, addressed the Medical Society of Washington County, Glens Falls, October 1, on "Differential Diagnosis of the Painful Abdomen" and "A Study of What Surgery Has Really Done for Cancer of the Breast," respectively.—Dr William T. Getman, Buffalo, addressed the Geneva Academy of Medicine, October 17, on toxemias of pregnancy.—Drs Arthur J. Wallingford and John C. McClintock addressed the Medical Society of the County of Albany, Albany, October 23, on "Auto Blood Transfusion" and "Differential Diagnosis of Hyperthyroidism," respectively.—Dr George H. Whipple, Rochester, addressed a joint meeting of the Rochester and Syracuse academies of medicine, October 17, on "Problems in Anemia."—Dr Edward M. Livingston, New York, addressed the Medical Society of Monroe County, Rochester, October 24, on "Abdominal Surgical Diagnosis."

New York City

New Cancer Unit in Preparation—A building formerly used as the children's section of the Kings County Hospital is being reconditioned by the municipal department of hospitals for use as a special cancer center. The new institution, which will take the place of the Brooklyn Cancer Institute now at Cumberland Hospital, will have an initial capacity of seventy-five or eighty beds with the prospect of 100 or more later. Dr Sigismund S. Goldwater, commissioner of hospitals, has appointed a committee to advise him on the selection of a staff. Dr John E. Jennings, chairman of the Brooklyn Cancer Committee, is chairman and members include Drs George A. Merrill, Mark L. Fleming, Ira I. Kaplan, Edward M. Bernecker, James Ewing and William Harris.

Flower and Fifth Avenue Hospitals Merge—Affiliation of the Fifth Avenue Hospital with Flower Hospital was announced October 17, after a meeting of the trustees of the former. The two institutions will be combined in the building of the Fifth Avenue Hospital, but for the present they will operate independently, though along parallel lines. Dr Claude A. Burrett, dean and professor of surgery, New York Homeopathic Medical College and Flower Hospital, has been named director of the hospitals. Mr David Q. Hammond, superintendent of Flower Hospital, will be superintendent. Flower Hospital, which has a capacity of 197 beds, was founded forty-six years ago, Fifth Avenue, with 300 beds, was organized in 1922 as a consolidation of the Laura Franklin Free Hospital for Children and Hahnemann Hospital. The present buildings of Flower Hospital will be utilized by the medical college.

Society News—Drs Arnold R. Rich, Baltimore, and James Alexander Miller addressed the Medical Society of the County of New York, October 28, on "Immunity in Tuberculosis" and "The Evolution of Pulmonary Tuberculosis," respectively.—Drs Charles C. Higgins, Cleveland, and James Dellinger Barney, Boston, addressed the New York Society of the American Urological Association, October 23, on "Experimental Production and Solution of Urinary Calculi" and "The Relation of the Parathyroid Glands to Urinary Calculi," respectively.—A symposium on the treatment of chronic constipation was presented before the National Society for the Advancement of Gastro-Enterology, October 23, by Drs Albert J. Sullivan, New Haven, Conn., Walter A. Bastedo, Michael G. Mulinos and Richard Kovacs.—Dr. Mark Gerstle Jr, San Francisco, addressed the New York Neurological Society, October 1, on "Congenital Stenosis and Atresia of the Aqueduct of Sylvius." Speakers at a meeting of the society with the section of neurology and psychiatry of the New York Academy of Medicine, November 12, will be Drs Milton M. Ables on "Nervous System Trichiniasis", Ira Cohen, "Posterior Fossa Tumors Without Papilledema," and Charles A. Elsberg, "The Value of Quantitative Olfactory Tests for the Localization of Supratentorial Lesions."

torial Tumors of the Brain"—Dr Thurston Scott Welton addressed the Medical Society of the County of Queens, October 29, on "Common Errors in the Practice of Obstetrics and Gynecology"

OHIO

Institute on Cardiovascular Disease—The Heart Council of Greater Cincinnati and the Cincinnati Academy of Medicine will hold their third annual Institute on Cardiovascular Disease at the Cincinnati General Hospital, November 12. Dr Paul D White, Boston, will give a clinical lecture with patients at the morning session and, after a luncheon at the University of Cincinnati College of Medicine, Dr Hugo Roesler, associate professor of radiology, Temple University School of Medicine, Philadelphia, will give a fluoroscopic demonstration of cardiovascular disorders. In the evening Dr Roesler will address the academy of medicine on "Recent Studies in the Treatment of Cardiovascular Diseases"

OREGON

Annual Registration Due December 1—All practitioners of medicine and surgery holding licenses to practice in Oregon are required by law to register annually on or before December 1, with the secretary of the Board of Medical Examiners, and at that time to pay a fee of \$5. A practitioner failing to register is subject to a penalty of \$1 for each thirty days, or part thereof, of default and his failure to reregister within ninety days after December 1 is a misdemeanor

PENNSYLVANIA

Personal—Dr Samuel J Dickey, who has been on the staff of the state department of health for about ten years, has been appointed medical director of Chester County.—Dr Howard F Straub, Selinsgrove, has been named medical director of Snyder County, succeeding Dr Russell W Johnston

Philadelphia

Society News—The Philadelphia County Medical Society will observe Pennsylvania State Health Day, November 13, by a special program with the following speakers: Drs Clarence A Patten, "The Effect of Noise on the Human Organism and Its Treatment", Joseph A Daly, "Apathy of the Medical Profession Toward Public Health Legislation", and Chauncey L Palmer, Pittsburgh, "Legislative Problems Affecting the Medical Profession and the Public."—Brig Gen Matthew A Delaney, Carlisle Barracks, addressed the section on public health and industrial medicine of the Philadelphia College of Physicians, November 8, on "The Army Officer and the Public Health."—The Philadelphia Allergy Society held its first annual meeting, October 30, with the following speakers, among others: Drs Philip S Stout, "Ionization of Nasal Mucous Membranes for Allergic Manifestations", Abraham Trasoff, "Value of Air-Conditioned Rooms in the Treatment of Seasonal and Perennial Asthma," and Louis Tuft and Isaac George Blumstein, "Incidence and Importance of Tree Pollen Hay Fever with Particular Reference to Philadelphia and Vicinity"

RHODE ISLAND

Society News—Drs Gordon Berry Worcester, Mass, and Adolph W Eckstein, Providence, addressed the Providence Medical Association, October 7, on "Our Deaf Children and How We Are Caring for Them" and "Emergency Treatment and Transportation of Fractures," respectively. A panel session on diabetic surgery was held, November 4. Dr Alexander M Burgess, Providence, was chairman and the speakers were Drs. Leland S McKittrick, Howard F Root and Shields Warren, all of Boston, and Lucius C Kingman, Providence.

VERMONT

State Medical Election—Dr Lester W Burbank, Cabot, was elected president of the Vermont State Medical Society at the annual meeting in October. Other officers are Drs John Trotter Jr, Bennington, vice president and William G Ricker, St Johnsbury, reelected secretary. Next year's meeting will be in Burlington. Dr Burbank was graduated from the University of Vermont School of Medicine in 1896.

WASHINGTON

Health at Spokane—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended October 26 indicate that the highest mortality rate (177) appears for Spokane and that the rate for the group of cities as a whole was 106

The mortality rate for Spokane for the corresponding week of 1934 was 12 and that for the group of cities, 106. The annual rate for the eighty-six cities was 11.4 for the forty-three weeks of 1935, as against a rate of 11.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

PHILIPPINE ISLANDS

Bill to Release Lepers Vetoed—Governor General Frank Murphy vetoed a bill adopted by both houses of the Philippine legislature, by which lepers would have been released from segregation in colonies. Governor Murphy held that, although the bill had a worthy purpose and certain meritorious features, it would create a situation menacing to the public health. Its first effect would be to return large numbers of lepers to their homes, where it would be difficult to prevent transmission of their infection to children now protected, he pointed out in his veto message. Furthermore, release of many of the lepers now maintained by the government would precipitate a serious social and economic problem. Governor Murphy said that he would appoint a commission to study the entire problem of leprosy control with a view to improving present methods.

PUERTO RICO

Society News—The annual meeting of the Puerto Rico Medical Association for the district of Guayama was held at Central Aguirre recently. Dr Antonio Navas-Torres, president of the district association, presided and papers were presented by the following physicians: Drs Ramon M Suarez, Esteban Garcia Cabrera, Oscar G Costa-Mandry and George C Payne, all of San Juan, Rafael Lopez Nussa, Ponce, and Jose B Gotay, Adjuntas.

GENERAL

Placement Bureau for Physicians—The American Association of School Physicians recently established a placement bureau to aid physicians meeting its qualifications to find desirable positions, and to recommend to educational institutions medical inspectors qualified to organize and administer an efficient program of health service and health education. Information may be obtained from Dr Arville O DeWeese, formerly president of the association and director of health and physical education, Kent State College, Kent, Ohio, who is director of the bureau.

Dr Houssay to Visit the United States—Dr Bernardo Alberto Houssay, professor of physiology at the National University of Buenos Aires, Argentina, will arrive in New York, November 18, for a tour of the United States, during which he will lecture in several cities on endocrinology. He will visit Boston, Cleveland, San Francisco and other California cities: Chicago, Toronto, Montreal, Washington, Baltimore, Philadelphia, New Haven and Rochester, Minn, leaving New York January 25. Dr Houssay left Buenos Aires September 8 and spent a month in Paris before visiting the United States.

Fellowship for Women Physicians—The Women's Medical Association of New York City offers the Mary Putnam Jacoby Fellowship of \$1,000 for one year for graduate work abroad in medical sciences. The fellowship is open to any woman graduate of an approved medical school. Each candidate must be endorsed by the head of the department in which she has done her previous work. The recipient must give full time to the research. Applications for 1936-1937 should be filed with the chairman of the committee by April 1, 1936, and must be accompanied by statements as to health, educational qualifications and proposed problem for investigation. A report for publication will be required at the completion of the fellowship. Dr Annie S Daniel, 105 East Fifteenth Street, New York is chairman of the committee.

New Editor of Journal of Syphilis—With the October issue, the *American Journal of Syphilis and Neurology* passed under new editorial management. With the first issue of the new volume to appear in January 1936 its title will become the *American Journal of Syphilis, Gonorrhea and Venereal Diseases*, and there will be six issues instead of four yearly, published at bimonthly rather than quarterly intervals. The omission of the words "and Neurology" from the title does not mean that the journal ceases to be interested in the neurologic aspects of syphilis, it was stated. The organization of the American Neisserian Medical Society seems to guarantee the widening of the journal's scope to include not only gonorrhea, but also chancroid, granuloma inguinale, lymphogranuloma

inguinale and other similar conditions, it was said Dr Joseph Earle Moore, Baltimore, is the new editor

Bequests and Donations—The following bequests and donations have recently been announced

Fifth Avenue Hospital and Woman's Hospital New York, \$59,000 and \$20,000 respectively Monmouth Hospital, Long Branch, N. J. \$10,000 by the will of the late Mrs. Mary T. Sheldon The residuary estate of undetermined value goes to the Society of the New York Hospital, New York

Mount Sinai Hospital New York named residuary legatee and received remainder and contingent interests in \$830,000 under the will of Edward J. King

Mount Sinai Hospital New York \$1,300,000 by the will of Bertha Weinman St. Vincent's and Presbyterian hospitals, New York, \$2,500 each

ankenau Hospital, Philadelphia \$1,000 by the will of Pauline Berges Episcopal Hospital of Philadelphia \$30,000 by the will of Mrs. Annie B. Moore

New York Eye and Ear Infirmary \$5,000 by the will of Miss Gertrude S. Thomas Morristown, N. J. who bequeathed also half her residuary estate to the New York Post Graduate Medical School and Hospital

Ashland General Hospital, Ashland, Wis. \$40,000 by the will of the late Frank Drummond

Mortality of the Blind—A survey of causes of death among blind persons, recently completed by the Metropolitan Life Insurance Company, reveals that the mortality is distinctly higher among these persons than among normal persons. The study was made over a ten year period and involved 11,716 industrial policyholders who were granted disability allowances because of blindness incurred subsequent to the issue of their policies. Diseases which themselves cause blindness were responsible for this high rate rather than accidents. The causes of death that showed the highest mortalities were syphilis and diabetes. The death rates for these were respectively more than twelve and seven times those of normal persons. Of the entire group, accidents were responsible for the blindness of 6 per cent. In the majority of cases, the blindness was reported as due to specific diseases of the eye, but study of the causes of death showed that the facts were not accurately reported in many cases and that the blindness was due to a general disease. The most frequently reported cause of blindness was cataract, second, glaucoma, and third, atrophy of the optic nerve.

Association of American Medical Colleges—At the annual meeting of the Association of American Medical Colleges in Toronto, October 28-30 a symposium on the basic sciences in relation to the physician's training was presented by Dr. Jacob Parsons Schaeffer, Philadelphia, Brenton R. Lutz, Ph.D., Boston, and Robert K. Cannan, D.Sc., New York. Harry N. Holmes, Ph.D., Oberlin College, Oberlin, Ohio. Edward C. Schneider, Sc.D., Wesleyan University, Middletown, Conn. In another symposium on undergraduate instruction, members of the faculty of the University of Toronto participated as follows: Drs. Duncan A. L. Graham, medicine, Alan G. Brown, pediatrics, William E. Gallie, surgery, John G. Fitzgerald, hygiene and preventive medicine, Clarence B. Farrar and Edward A. Bott, B.A., psychology and psychiatry. The program also included discussions of the teaching of pharmacology and therapeutics and the internship as a problem in medical education. Dr. Stanley Ryerson, Toronto was chosen president-elect of the association and Dr. John H. Wyckoff, New York, was installed as president. Dr. Russell H. Oppenheimer, Atlanta, Ga., was elected vice president, Dr. Arthur C. Bachmeyer, Chicago, treasurer, and Dr. Fred C. Zapffe, Chicago, was reelected secretary. The next meeting will be held in Atlanta, Ga., Oct. 27-29, 1936.

Southern Medical Association—The twenty-ninth annual meeting of the Southern Medical Association will be held in St. Louis, November 19-22, at the Municipal Auditorium. Tuesday will be "St. Louis Day," when all the programs will be presented by St. Louis physicians. Wednesday morning there will be four sessions meeting concurrently representing all specialties. At these sessions speakers will include, among others: Dr. James Tate Mason, Seattle, President-Elect of the American Medical Association, who will discuss "Some Modifications of the Technic in Surgery of the Common Duct," and Dr. James S. McLester, Birmingham, President, American Medical Association, "The Emotional Factor in Clinical Problems." Fifteen sections will hold meetings, and organizations that will hold annual meetings in conjunction with the association include: American Society of Tropical Medicine and the National Malaria Committee, regional sections of the American Public Health Association, the American Academy of Pediatrics, the Society for Experimental Biology and Medicine, Southern Association of Anesthetists, Mid-Western Association of Anesthetists and the International Anesthesia Research Society will also convene during the week. The annual golf tournament will be at Meadow Brook Country Club Tuesday, Wednesday and Thursday, the tenth annual trap shooting tournament Wednesday afternoon. Dr. H. Marshall Taylor, Jacksonville, Fla., is president of the association.

Psychiatrists Warn Statesmen of War Psychosis—An analysis of the war spirit and a warning against the development of a "war psychosis" are set forth in a document recently drawn up by more than 300 psychiatrists from many countries and sent to leading statesmen of the world under the auspices of a "committee for war prophylaxis" of the Netherlands Medical Association. Declaring that the science of psychiatry has advanced to a point at which psychiatrists are able to distinguish between real, pretended and unconscious motives the statement asserts that arguments for war advanced by well known statesmen camouflage a primitive craving for power. In spite of the conscious individual aversion to war, "civilized twentieth century man still possesses strong, fierce and destructive instincts which have not been sublimated or only partly so and which break loose as soon as the community to which he belongs feels itself threatened by danger," it continues. Peoples under the influence of the warlike spirit in their leaders may become neurotic and may be carried away by hallucinations and delusions, thus involving themselves in adventures perilous to their own and other nations' safety, the document explains. It urges the statesmen to arouse the peoples to a realization of the intrigues of the international traffic in arms and to a sense of collective self preservation, the popular ideas of war as they find expression in dress uniforms and military display are no longer in keeping with the realities of war itself. The psychiatrists express the belief that international organization is sufficiently advanced to enable statesmen to prevent war by concerted action, but they urge that if any statesmen think that the apparatus to ensure peace is not strong enough they should devote to this purpose as much energy and as much money as is now being expended on armaments. Among the signers of the document are Drs. Charles Macfie Campbell, Boston, Alfred Gordon, Philadelphia and Aaron J. Rosanoff, Los Angeles.

Government Services

Award of the Wellcome Prize

Major Leon A. Fox, Medical Corps, U. S. Army, stationed at Baltimore has been awarded the Sir Henry S. Wellcome Prize and Medal for 1935 for his work on field chlorination of water, Science reports. The award, a gold medal and a prize of \$500, is made by the Association of Military Surgeons.

Course in Aviation Medicine

A course in aviation medicine for medical reserve officers was started at Cornell University Medical School, New York, September 1, to continue for six months under the direction of Lieut. Comdr. Julius F. Neuberger, medical corps, U. S. Navy. The practical work of the course is being given by Lieutenant Commander Neuberger at the headquarters of the third naval district, where all candidates for aviation in the U. S. Navy are examined. Lectures are being given by officers of the medical reserve corps who are professors or assistant professors connected with various institutions in New York. Recent lecturers are:

Lieut. Comdr. Aaron E. Parsonnet, Newer Methods in Electrocardiography
Lieut. Comdr. Philip R. Lehrman, The Structure of Neurosis
Lieut. Comdr. Page O. Northington, Function of the Internal Ear
Dr. John D. Reichard, surgeon U. S. Public Health Service, Signs and Manifestations of Organic and Functional Diseases of the Nervous System
Lieut. Comdr. Albert S. Hyman, Pathology of the Heart

Examination for Public Health Consultants

The U. S. Civil Service Commission announces competitive examinations for various grades of public health consultants and for public health research assistant to fill vacancies in the Children's Bureau, Department of Labor, and the U. S. Public Health Service both in Washington and in the field. Optional subjects for the public health consultants are maternal and child health, general public health practice and orthopedics. For the research assistant the specialty must be maternal and child health. Entrance salaries for the consultant positions range from \$2,600 to \$4,600 a year and the entrance salary for the research assistant is \$2,000. Certain education and experience are required. Information may be obtained from the civil service board of examiners at the postoffice or customhouse of any city that has a first or second class postoffice or from the commission at Washington. Applications must be on file not later than November 25.

Too Much Administrative Work

In his presidential address to the Society of Medical Officers of Health, Dr W G Savage said that when the public health service of today was compared with that before the war, it was found that on the whole the work was less interesting and less stimulating. It was likely to become even less so if developments took place along the lines which experience suggested as possible. The tendency was for the senior men, those who had become heads of their departments, to become more and more purely administrators. It was a commonplace that the function of public health was preventive. While they had their feet planted on the broad road of preventive medicine, they were being induced and officially directed to squander their energies by incursions into side roads which, while occasionally profitable, prevented progress to their real goal being other than deplorably slow. One of the difficulties of putting preventive medicine into practice was its necessary relation to the inflexibility of the law. Enmeshment in mere administration and close relation to rigid legal requirements were definite obstacles.

The special training and wide experience of health officers entitled them, and should compel them, to survey the whole field of preventive medicine and to exert their influence in making the practice of public health more scientific in outlook and more effective in operation. In some way or other they must shed a good deal of the present burden of pure administration to enable them to carry out their life work. This could be done only by the use of a new and different kind of administrator, responsible to but strictly subordinate to the head.

With regard to junior members of the service, he had sympathy with certain grounds of dissatisfaction. In the main their duties were confined to clinical work, chiefly school medical inspection and attendances at maternity and child welfare clinics. In the large clinics and in most counties the work of newly appointed officers was almost entirely dissociated from preventive medicine proper and without any opportunity to take part in its broader activities. This work had to be carried on, but he hoped that he would see extensive modifications. It was one of the valid arguments for the transfer of much of this work to the private physician that it would tend to shorten the long road of the health officer from obtaining his diploma to his appointment as health officer. An alternative possibility was to alter materially the basis of some of the work, especially school medical inspection and maternity and child welfare work. With adequately trained, competent infant visitors, most of the work should be done by them in the homes, and the health officer could restrict his activities to selected cases.

The Smoke Evil

At a meeting of the Edinburgh and East Scotland sections of the Society of Chemical Industry, John du Plessis Langrishe, lecturer in public health at the University of Edinburgh, complained that while meticulous care was bestowed on the control of the purity of food and water, little was exercised over the purity of air. Statistics showed a close relation between death rates and atmospheric conditions. The number of deaths from pulmonary and cardiac diseases increased in direct proportion to an increase in the intensity and duration of smoke fogs. At the extremes of life these effects were most marked. The lungs of city dwellers became blackened like those of a coal miner. Increased tuberculosis of the lungs was produced. There was also good ground for believing that the

tarry matter of smoke was at least partly responsible for the increase of cancer of the lung. Another evil was obstruction of solar radiation. On a still day Manchester received only 55 per cent of the daylight received by Temperley, only six miles south. On a foggy day it received 5 per cent. The ultraviolet rays were affected to an even greater extent. Manchester received only 26.9 per cent of the radiation enjoyed by Hale, nine miles away. City dwellers were stunted because of the reduced ultraviolet radiations being insufficient to produce assimilation of calcium and phosphorus. Rickets and anemia resulted. Psychologic ill effects were interrelated with the physiologic. Smoke gloom lessened the potential reserve, working power and well being of the individual. It had been shown that the pasturage of the industrial towns in Lancashire, which at one time supported two cows to the acre, could now carry only one cow to three acres, while the milk was deficient in calcium. Garden produce also was affected by the smoke. Lettuce grown under such conditions gave only 31 per cent of the natural yield and was deficient in quality.

In the discussion Mr A M Ritchie, chief sanitary inspector of Edinburgh, said that Edward I believed that smoke affected his health. He issued a proclamation forbidding the use of coal while parliament was sitting and it was related that a man was hanged in the fourteenth century for causing a smoke nuisance. But even this penalty was not effective, as shown by the constant reference to the evils of smoke in the following centuries. For years the main efforts in smoke abatement had been directed to reducing factory emissions, with excellent results. But to effect any real improvement in atmospheric conditions, attention must be paid to the pollution caused by the domestic fireplace. The British people had a persistent partiality for the open fireplace. The aim of the future must be to replace the burning of raw coal by smokeless fuel.

Speaking at a York Health Week, Mr Marsh, general secretary of the National Smoke Abatement Society, said that York needed smoke abatement not only for the health of its citizens but also for its minster (the cathedral). Smoke deposits had created cavities in the stone work more than 9 inches deep. York was unfortunate in that it lay on the line of the prevailing wind from the West Riding industrial area, where the atmospheric conditions were appalling. The coal industry was striving to evolve a smokeless fuel that would make it possible to impose really effective penalties on the domestic chimney.

The Public Health

The annual report for 1934 of the chief medical officer to the Ministry of Health has just been published. It shows that even in the most distressed areas the measures taken by public authorities and the generous efforts of individuals have, so far as the usual indexes of health can be trusted, largely held in check the deleterious influences of unemployment and reduced income. But it is added, "At the same time the report gives no ground for complacency. No inquiry can accurately evaluate the grave indirect dangers to health of mind and body which prolonged unemployment involves." Last year's vital statistics are most satisfactory. The death rate was 11.8 per thousand of population against 12.3 in 1931, 12 in 1932 and 12.3 in 1933. The lowest rate yet recorded was 11.4 in 1930, in 1928 the rate was 11.7 in 1926, 11.6. The rates of infant mortality are equally satisfactory. The rate last year was the lowest ever recorded, 59 deaths of children under 1 year of age per thousand births. Previous rates show an almost constant decline: 1926, 70; 1928, 65; 1930, 60; 1931, 66; 1932, 65; 1933, 64. The rate from 1911 to 1915 was 110, from 1916 to 1920, 90; from 1921 to 1925, 76. It is therefore obvious that young children are being better fed and cared for than ever before, in spite of world conditions, of unemployment and of a change in the age constitution of the population, which places on the shoulders of young fathers a heavier burden of care for aged

relatives The birth rate, which has been steadily falling since 1880 (from 35.4 per thousand to 14.4 in 1933) rose slightly, to 14.8

THE CAUSES OF DEATH

Among the causes of death among persons between 15 and 65 years of age the following are the most important

| | Proportion per 1,000 |
|---|-------------------------|
| 1 Diseases of the heart and circulation | 207 |
| 2 Cancer | 168 |
| 3 All forms of tuberculosis | 139 |
| 4 Bronchitis pneumonia and similar conditions | 94 |
| 5 Diseases of the nervous system | 78 |

There was during 1934 a marked fall in the incidence of pneumonic diseases, cerebrospinal fever, typhoid, smallpox and acute poliomyelitis The high incidence of scarlet fever and diphtheria that characterized the autumn of 1933 persisted into 1934 Scarlet fever has for many years been of a mild type, but a grave form of diphtheria is again in evidence Cases of this grave form occur in some districts simultaneously with cases of a mild form in other districts The death rate from tuberculosis was the lowest ever recorded This is regarded as showing that the efforts to secure better houses and better food, especially the supplying of milk to school children, are producing lasting benefit Little progress has been made in dealing with the undiminishing maternity mortality, but study is now proceeding, and it is held that lack of antepartum care and expert help and advice are important contributory causes

A British Ambulance Service for Ethiopia

A British ambulance service is being formed for Ethiopia under the Geneva convention. It is working in consultation with the International Red Cross at Geneva The executive committee has made preliminary arrangements so far as funds privately subscribed have permitted It has secured a tentative panel of physicians, and further applications are invited An officer has been dispatched to recruit native personnel in Kenya and Uganda. The committee is represented at Addis Ababa by a missionary of thirty years' standing, who has the complete confidence of the emperor It is estimated that the complete cost of a properly equipped ambulance, consisting of one clearing station and one field hospital with seven surgeons and the necessary native dressers, including vehicles for transport and maintenance for three months, would be \$175,000 Each additional casualty clearing station would cost a further \$50,000

PARIS

(From Our Regular Correspondent)

Oct. 4, 1935

The Medical Societies of Paris

The list of the meeting places, dates of first meetings and days on which each medical society of Paris holds its regular sessions during the coming winter has just appeared (September 28) There are forty societies in Paris, representing every special field of medicine. Admission to the majority is granted on submission of qualifications, based on hospital and faculty positions, previous publications in a specialty and the reading of an inaugural thesis based on personal clinical experience or research work.

At least half of the forty societies publish their proceedings in a weekly or monthly bulletin Many of the papers read at these meetings appear only in such a bulletin. Often the visitor is astonished to note that fifteen or twenty communications are announced for a given meeting and one wonders how such a large number can be read in a period of one or two hours At one of the most important weekly meetings, that of the Société de biologie, only abstracts of research work are permitted to be read As often occurs in continental medical societies, conversation does not cease in the audience, and the foreign visitor is astonished The publication of the papers in abstract, within

a week after the meeting, allows the audience to postpone reading the papers until they are published This system of issue of complete reports of the society proceedings is more highly developed in Paris than in any other continental medical center

Societies such as the Société nationale de chirurgie, Société de biologie, Société médicale des hôpitaux, Académie de médecine and Académie des sciences have a fixed day every week for meetings The majority of the other societies meet once a month, and a few meet twice a month Members of the societies sit in an enclosure and visitors sit in a separate part of the auditorium

It is unfortunate that the proceedings of many of the societies are published only in the corresponding bulletins, because much of the material is thus rendered inaccessible to those who wish to keep abreast of the splendid work being done in Paris Only longer articles are published in the journals accessible to the medical profession in foreign countries

The Employers' View of Social Insurance

An article in *l'Information*, a financial daily of Paris, September 26, cites a letter written by Henri Garnier, president of the Association of the Chambers of Commerce of France, to Mr Frossard, secretary of labor, whose department administers the social insurance law The essential features of the letter are as follows

"The Chambers of Commerce have frequently protested the surcharge on national economy of the social insurance law and have been pleased to see that some radical reforms are being introduced There is urgent need of a reduction in the premiums paid by the assured and his or her employers Simplification of the application of the law is also urgently needed. Recovery from the present economic crisis affecting France depends more than ever on lightening the burden that is at present checking business and financial circles Some headway in this direction has been made by the government in a cut in salaries of officials, by suppression of certain taxes, and by similar measures A reform of the social insurance law should have the same objective. It would seem wise to suspend or make optional the application of this law until better times come back.

"Extension of the law to those who work at home should by no means be considered at present In the past four years, more than 17 billion francs (nearly 700 million dollars) has been sequestered from the national economy and this must be regarded as playing an important part in the present crisis

"It is futile to give salaried workers the illusion of old-age pensions in the distant future and at the same time take money away from them by ruining the establishments where they are employed, resulting in unemployment and thus making it difficult to earn a living at the present time."

Should a Physician Be Compelled to Retire at a Certain Age?

In the August 25 *Concours médical*, Noir quotes a letter sent out by the executive committee of the "University Statistical Bureau" stating that "a resolution had been voted unanimously to the effect that compulsory retirement from all professional or technical work should be demanded, provided a general pension plan could be elaborated. The attention of the French medical profession should be called to such a movement and their aid in its accomplishment asked for"

Noir states that a demand has been frequently made to have every physician retire at the age of 60 Many practitioners would be happy to comply, having earned a rest after many years of active work The majority, however, still have heavy financial burdens to bear at the age of 60, such as children whose education has not been completed or who cannot earn their own living Even if the two latter conditions have been fulfilled, a retired physician at 60 could not ask his children to support him.

Siredey, president of the French Academy of Medicine, is quoted as saying that, under present conditions, an age limit is not feasible for the liberal professions, especially for medical

men who are obliged to practice during their entire life. From the legal point of view it would be impossible to state in granting a diploma that its possessor might practice only during a certain number of years. Members of the faculties of medical schools in France, military surgeons and those connected with other public medical institutions are provided with a pension at the age of retirement. This is not true of the attending staffs of free hospitals and other charitable organizations. In order to provide a pension equivalent to two thirds of what a physician had earned annually in the six years prior to retirement at sixty, it would be necessary for him to pay premiums during a fixed number of years of active practice. Statistics of such old-age pension associations in France show that comparatively few physicians are able or at least are far sighted enough to avail themselves of such insurance. In the case of government officials, 5 per cent of their salaries is deducted to pay for pensions on retirement. One cannot compare a physician to such a government official. The only solution would be for every medical man to become a salaried officer of the state, and this is a condition hanging over the heads of the profession in France.

BERLIN

Compulsory Attendance on Graduate Medical Courses

The federal fuhrer of physicians has now announced the rules that are to govern compulsory attendance on graduate medical courses. The administration of this obligatory instruction has been entrusted to the provincial leaders of the *Kassenärztliche Vereinigung Deutschlands*, who will designate the physicians who are to be summoned to take the various courses, will distribute the physicians among the various courses, and will supervise the conducting of the courses. The system of graduate instruction at present affects the Aryan general practitioners located in places of less than 100,000 population. The physicians in larger cities, and the specialists, will be brought into the system later, under different regulations. According to the rules, every physician in a place with fewer than 100,000 inhabitants must take a graduate course at a hospital every five years during the period from April to November. Each course will continue for three weeks. As a rule, physicians chosen to take given courses will be notified at least two months in advance. Physicians will be assigned to hospitals or cities with which they ordinarily have no contacts, the idea being that the physician will be freer to act with relation to the hospital director and to the patients. An endeavor will be made to afford the participants an opportunity for training in branches in which they feel themselves deficient. Internal medicine will be given the chief emphasis, but participants will be allowed to look around in other departments.

As a rule, practitioners will substitute for one another during the months in which certain colleagues are participating in these graduate courses, but in some instances "assistant physicians" in hospitals will be permitted to serve as *locum tenentes*. Such an arrangement may be frequently feasible owing to the fact that young physicians must, according to the new requirements, serve for three months in a country practice before they are admitted to panel practice. The expenses connected with the appointment of a *locum tenens* must be borne by the participant in the graduate courses, in addition he must pay 2.50 marks (\$1) a day for his maintenance in the hospital.

The graduate instruction will be organized as follows. Physicians taking the courses will be distributed in small groups among the various hospitals, in which they will obtain board and room. The participants in the graduate courses will each be given a number of patients to care for, with the cooperation of the chief physician. They will not, however, be strictly bound by the service hours, as is the assistant physician," but

will have an opportunity to inspect other departments and to do such work as seems most profitable to them. Importance will be attached to participation in pathologic births. In addition to the graduate training at the sick-bed, there will be clinical lectures and practical drills, together with presentation of patients, to which all the participants in the city will be summoned. Exact records will be kept of the attendance at lectures, and physicians will receive certificates as evidence of their participation in the courses. From 9 to 1 the work in the various hospital services will be accomplished, and afternoons from three to four hours will be devoted to lectures in the different fields of medicine, according to a definite schedule. For the afternoon lectures a long list of subjects that seem important has been chosen.

Diphtheria in Children's Homes

In consequence of continual outbreaks in various regions, diphtheria receives considerable attention, especially where children are found in homes conducted by the welfare societies. The minister of the interior has ordered that in such homes only persons who are healthy and are not carriers of diphtheria bacilli shall be employed or sheltered. Evidence of the health of all occupants of the homes must be furnished through a medical or bacteriologic examination. Every new applicant for employment in such a home must present a medical certificate which guarantees that the examinee is free from diphtheria bacilli. Likewise, children and juveniles who are about to be admitted to such homes must be examined before starting on their journey, to exclude carriers of diphtheria bacilli. Before children may be sent from regions in which there is a high incidence of diphtheria, the consent of the local bureau of health must be secured, to obviate the danger of transmission of the disease to the homes.

Medical Care of Needy Patients

Heretofore the medical care of charity patients in the German reich has been anything but uniform. The diverse local agreements between the physicians and the communes have led frequently to misunderstandings. Uniform regulations have now been adopted. The chief objectives that determined the nature of the regulations were the creation of an adequate and satisfactory system of medical care of needy patients, the introduction of an economical method of furnishing medicines and sanitary supplies that would be in keeping with the general principles of welfare work, and the substitution when feasible of domiciliary care for hospital treatment.

All panel physicians within the limits of the local welfare league will be admitted to welfare practice. The needy persons who come under the jurisdiction of a given welfare league have the right to choose their physician from among the physicians affiliated with that league, provided they have secured a so-called treatment certificate. Physicians admitted to welfare practice are under obligations to treat all needy applicants (provided with a certificate) during their office hours or, if necessary, in their homes. The scope of the treatment comprises most forms of medical aid, including night service. Dental treatment is not included. Permits for admittance to a hospital require special authorization and are issued by the welfare league. Hospital care is to be authorized only when an operation is involved that is not commonly performed outside an institution or when adequate treatment can be given only in a hospital. Strict economy must be exercised in the prescribing of medicines. Proprietary foods and tonics, for example, must not be prescribed, and "patent remedies" may be prescribed only when they are inexpensive. The welfare league may, if it desires, specify in the treatment certificate the nature of the medicines that may be prescribed. A price schedule is set up to govern the cost of medical treatment. In the event that these regulations are violated, the cost of a remedy unlawfully

prescribed can be deducted from the physician's fee. The welfare leagues are urged to establish centers for the validation of prescriptions and also a system of medical supervisors. To supply funds for the payment of physicians' fees, the welfare league transmits monthly to the *Kassenärztliche Vereinigung Deutschlands* a certain sum based on experience tables set up as the result of somewhat complicated computations.

VIENNA

(From Our Regular Correspondent)

Oct. 2, 1935

The Society for the Promotion of an Increase of Population

The low birth rate in Austria, and particularly in Vienna, induced the *Oesterreichische Gesellschaft für Bevölkerungspolitik* to choose as the main topics for discussion at its sixteenth session "The Dearth of Children" and "The Family." Some 400 statisticians, political scientists, pediatricians and juvenile-welfare workers attended the session, to discuss the problems thereby involved. The session was held recently under the chairmanship of Prof. Dr. Reichel of Graz, who gave an address on "Healthy Posterity." He pointed out that the number of children in Austria is much less than are necessary to preserve the status quo of the population. What is needed is not only a reduction of taxes payable by the heads of large families but also the removal of various hindrances to marriage. Women should be given an opportunity to quit industrial life and return to the duties of rearing a family. The persons on whom rests the moral responsibility for childless marriages should be revealed. The government should facilitate the contraction of marriages and the rearing of families by improving the housing situation and prohibiting the use of contraceptives. The funds for such undertakings might be secured by the imposition of heavy taxes on inheritances and on bachelors. Prof. Dr. Winkler, head of the department of statistics, analyzed the results of the census of 1934 in its bearings on the present status of the family. The statistics reveal that in Austria as a whole, for the marriages contracted since 1890 the average number of children is 1.8 children to the family for first marriages (of both spouses), 2.4 children to the family for multiple marriages (two or more), and 1.7 children for broken families (due to death, separation or divorce). For Vienna the figures are: average number of children to the family, 1.3, average number of children to the family for first marriages, 1.2, average number of children to the family for multiple marriages (two or more), 1.6, and average number of children to the family for broken families, 1.3. It is an established fact that four children to the family are necessary to bring about an increase of the population and three children to preserve the status quo. Two children to the family will not suffice for the population to hold its own, for, while in a sense the number of married persons are being replaced, the considerable number of unmarried persons are not being reproduced. In Austria, since 1890, more than 25 per cent of the marriages have been childless, 25 per cent of the remainder have yielded only one child, 20 per cent have produced two children, 12 per cent three children, and 16 per cent four or more children. In Vienna 33 per cent of the marriages have been childless, 33 per cent have yielded only one child, and only 6 per cent have produced four or more children. Similar conditions are found in other large cities of the republic and likewise in the immediate vicinity of the large cities, even though a region is inhabited by an agricultural population. This downward trend, which, it is feared, has not yet touched bottom, constitutes a grave menace for Austria.

The problem of illegitimate children was discussed by Dr. Hecke. The total number of births averaged during the period 1920-1925 more than 150,000, but during the period 1930-1933

it has dropped below 100,000. The illegitimate children have decreased from 31,000 births to 25,000, although their percentage has risen from 21 to 26. Since 1926 the total number of living births in Austria has dropped to 76 per cent of the former status, while the total number of illegitimate births has dropped to 83 per cent of the former total. In Vienna the total number of living births has dropped to 53 per cent of the status of 1926, while the total number of illegitimate births has declined to 56 per cent of the former total. In the mountainous agricultural portions of the country the percentage of illegitimate births is much higher than in the cities. In Carinthia, for example, 42 per cent of the children are born out of wedlock. Likewise, the age at marriage in the rural sections is usually higher than in the cities. Thirty per cent of all the brides in 1900 were more than 30 years old, in Vienna only 22 per cent. That is the consequence of the peculiar mentality of the Alpine peasants and the unusual property rights obtaining in that region, whereby early marriage is rendered extremely difficult. The comparatively favorable position of illegitimate children among the peasants tends also to slow up the marriage zeal. Nevertheless it should be noted that the infant mortality among the illegitimate children is a third higher than among the legitimate children. The care that the latter receive is, after all, better and in the interest of public welfare an earnest endeavor should be made to facilitate marriage in rural circles.

Vital Statistics for Vienna

An interesting sidelight on the foregoing report is furnished by the following statistics, issued by the Vienna board of health as of June 1935. In that month 931 living births were recorded in Vienna, 751 of which were legitimate and 180 illegitimate (barely 20 per cent). Only 102 births took place at the home of the mother, the remaining 829 births occurred in hospitals or other maternity institutions. For that month eighteen stillbirths were reported. The deaths for that month numbered 45, 34 infants having died in the first month of life and 11 in the second month. The total mortality for the month was 1,900, in 377 cases organic heart disease was the cause of death, 315 persons died from cancer, 169 from respiratory tuberculosis, 126 from pneumonia and pleuritis, 99 from arteriosclerosis, 98 from hemorrhagia cerebri, 35 from senile weakness, and 27 from epidemic disease. One thousand and ninety-three of the deceased were more than 60 years old, 75 persons committed suicide. There were 1,739 marriages.

Treatment of Uncontrollable Hiccup

Uncontrollable singultus, the extremely tormenting and also dangerous disorder, which occurs occasionally as a postoperative complication, was discussed by Dr. H. Körbl at one of the recent sessions of the Vienna Surgical Society. He presented a patient who, on the third day after a cholecystectomy, developed an uncontrollable singultus. It was assumed that pressure of the retractor on the diaphragm during the operation had precipitated the disorder. An endeavor was made to control the singultus by the induction of vomiting, by sneezing, by stomach lavage, by the induction with drugs of sleep, by pressure on the diaphragm, and by bilateral blocking of the phrenic nerve but without result. As the condition had lasted ten days and the ingestion of food was prevented by uninterrupted hiccup, infusions of a mixture of sugar and sodium chloride were given. On the basis of the observation that carbon dioxide has a stimulating effect on the respiratory center during inspiration and produces normal rhythmic contractions of the diaphragm, an attempt was made to overcome the impulse toward abnormal contractions of the diaphragm by allowing the patient to breathe carbon dioxide. The effect was good. The singultus ceased with the first inspirations—at first for a short time, and then, on repeated application of the carbon dioxide, for increasingly long periods, so that the patient could eat and sleep. After four days the singultus had completely disappeared.

During the discussion that followed the demonstration, the good effects of this treatment were confirmed by Lotheissen and by Starlinger. It is true that good results may be secured by medicinal treatment, for example, the administration of from ten to fifteen drops of a 10 per cent alcoholic solution of menthol in water, several times a day. It appears, however, that the carbon dioxide procedure, which was proposed by Sheldon in America in 1928, has never gained wide publicity in this country, otherwise well known surgeons would not have seen fit to divide the phrenic nerve or to remove the fourth to the sixth cervical roots. Carbon dioxide had been administered to this patient after the operation, but that did not prevent the appearance of the singultus after several days.

CAPE TOWN

(From Our Regular Correspondent)

Aug 30, 1935

The Annual Medical Congress

The twenty-ninth South African Medical Congress, the eighth to be held under the auspices of the South African Medical Association, established in 1926, opens at Graham's Town, in the Cape Province, September 30. The president is Dr J M Beyers of Somerset East, a general practitioner, South African born and educated at Edinburgh. The chief discussion will center round the interesting question whether or not white civilization is progressing or deteriorating in South Africa. Various replies, mostly pessimistic, have been given to this question, but heretofore there has been no opportunity to discuss the available data frankly and to consider their implications apart from political and sentimental considerations. Another subject for debate will be the social and forensic aspects of dagga (*Leonotis*) smoking. At present dagga is classed in the same category as Indian hemp, as a habit forming drug, and its use by natives is severely punished. There is a difference of opinion about its toxicity, some observers claiming that it has no stupefying properties. A more serious allegation is that many specimens of dagga impounded by the police are not specimens of dagga at all but of quite different plants. A third subject for discussion will be the methods of fighting cancer. Much publicity has of late been given to the alleged increase of cancer in this country, but recent statistics do not show that this increase is out of proportion to the average increase of age. A paper by Dr Berman on the incidence of cancer among the Bantu tribes shows that the commonly accepted view that malignant disease is rare among non-Europeans in this country is erroneous. Dr Berman found that sarcomas were rare among natives on the Rand but that carcinomas were not uncommon. A justifiable criticism of his paper is that his statistics deal with a selected group of natives and do not apply to the native within tribal limits.

Senecio Poisoning

In 1920 Robertson and Willmot published a paper in the London *Lancet* describing what they assumed to be cases of poisoning by senecio seed. Previously several veterinarians had described symptoms similar to those mentioned in Robertson and Willmot's paper occurring in animals, mainly horses, that had fed on senecio plants. The cases in human beings came from a district where senecio was a frequent weed of the wheatlands, and the writers assumed that the seed contaminated the wheat flour. The patients, children or adolescents, suffered from abdominal distention, ascites, enlarged liver and diarrhea. The liver changes post mortem were similar to those found by Theiler in horses that had died of senecio poisoning. This year three patients, a father and two children, were admitted to the New Somerset Hospital from a 'senecio district' with a tentative diagnosis of senecio poisoning. Their symptoms resembled those of acute yellow atrophy of the liver. At the postmortem examination hemorrhagic atrophy of the

liver, portal venous obstruction, ascites with effusion into all serous sacs, peritonitis and collapse of the lung were found. The necropsy showed the liver when cut to have an appearance like that in chronic passive congestion, with the liver substance gone and the spaces filled up with blood. Frozen sections showed that the liver cells had disappeared in the center of the lobules and round the sublobular hepatic veins, these areas being completely hemorrhagic, while in some areas this destruction of liver cells had been followed by fibrosis, so that there was a developing cirrhosis, irregular in distribution and not definitely portal. The description reminds one of the subacute hepatic cirrhosis in young adolescents reported by French writers and said to be familial. While the senecio etiology is generally accepted here, there are several arguments against it. One is that the seed of senecio is a feathery pappus, not at all likely to contaminate wheat, as the slightest breath of wind wafts it away, another is that the specific poison of senecio—senecifoline—is not found in the seeds but in the vascular bundles of the young plant before flowering. It is easy to understand how grazing animals, eating young senecio plants, may be poisoned, but it is difficult to postulate senecio poisoning on the assumption that it is caused by the eating of bread baked from flour containing only a small proportion of senecio seed. It is to be hoped that the condition will be made the subject of special investigation.

Vital Statistics

The vital statistics published by the census office range over a period of twenty-three years, from union in 1910 to 1933. They concern the European population almost exclusively and are based on the census returns. As such they must be accepted with caution but nevertheless are interesting. They show, for instance, that in South Africa, as elsewhere, the average expectancy of life has steadily increased, that on the whole the mortality and birth rates are satisfactory, while the illegitimate birth rate is lower than in most civilized countries, with the exception of Holland and the United States, that the suicide rate is increasing and that juvenile marriages among the Europeans are still common. The disease with the highest number of fatalities is heart disease, even when rheumatic heart disorders are excluded, the second is pneumonia, the third cancer and the fourth tuberculosis. Cancer kills only ninety-three South Africans (Europeans) out of every 100,000, and these are all over 45 years of age. As an economic disease it is therefore not comparable to malaria, which, although it kills a far smaller proportion, incapacitates an immeasurably greater number and is of far greater economic and communal importance than malignant disease.

Kala-Azar

No case of kala-azar has as yet been reported from South Africa. A recent editorial in the *South African Medical Journal* suggests that the cases of enlarged spleen found in children in the coastal areas in which no definite cause can be ascertained may be cases of leishmaniasis, similar in type to those reported from the Mediterranean littoral and from Brazil. So far, however, no confirmation of this suggestion has been obtained, although spleen and liver puncture and examination of the bone marrow are now routine procedures in hospital cases in which kala-azar is suspected. From Bechuanaland has been reported the presence of trypanosomiasis among natives in the Ngami area to the north. Prompt steps have been taken by the protectorate authorities to deal with the disease and to limit its incidence to a small strip of marshy land. The importance to the union of trypanosomiasis in the Bechuanaland area is the fact that the mines draw some of their natives from this part and that if trypanosomiasis is once established in our native territories it would be almost impossible to eradicate it.

Marriages

THEODORE LAWRENCE GREENWALD, Orange, N J, to Miss Beulah Adele Durham of Maplewood, August 3

MARY C FOCHTMAN, Cozad, Neb, to Mr Laurence McNerthney of Tacoma, Wash, August 24

VICTOR A SIMIELE, Logan, Ohio, to Miss Mary M Foley of Columbus at Rochester, Minn, August 10

LAWRENCE PAUL JONES, North Emporia, Va, to Miss Emily Layfield Kitchin of Courtland, August 19

ALBERT D ROBERTS to Miss Lucille Gordon, both of Fort Worth, Texas, at Stephenville, August 8

THOMAS NORRIS GRAHAM, New York, to Miss Anne Tusten at Beverly Hills, Calif, August 21

JEFFERSON NEAFIE RICHARDSON to Miss Margaret Allen Pole, both of Philadelphia, July 24

WILLIAM K STROTHER JR., Dallas, Texas, to Miss Drusilla McCullough, August 22

VICTOR HILL, to Miss Gladys Miliken, both of Knoxville, Tenn, August 29

CHARLES B ODOM to Miss Anna May Manthey, both of New Orleans, in July

Deaths

Adolph Barkan, Zurich, Switzerland, Medizinische Fakultät der Universität Wien, Austria, 1866, member of the California Medical Association, the American Academy of Ophthalmology and Oto-Laryngology and the Pacific Coast Ophthalmological Society, professor of structure and diseases of the eye, ear and larynx, emeritus, Stanford University School of Medicine, San Francisco, formerly professor of ophthalmology and otology, Medical College of the Pacific and the Cooper Medical College, San Francisco, for many years eye and ear surgeon to the Lane Hospital, San Francisco, aged 90, died, August 28, of pneumonia

Rae Elsworth Houke ♂ Major, U S Army, retired, Glendale, Calif, Starling Medical College, Columbus, 1913, served during the World War, entered the medical corps of the U S Army as a first lieutenant in 1919, in 1929 was made a major, and retired in 1932 for disability in line of duty, aged 44, died, August 22, in the National Military Home, of coronary occlusion and cerebral arteriosclerosis

Alois Jokl, Lackawanna, N Y, Niagara University Medical Department, Buffalo, 1892, member of the Medical Society of the State of New York, aged 75, past president of the city board of health, formerly health commissioner in Lackawanna, on the staff of Our Lady of Victory Hospital, where he died, September 24, of carcinoma of the gallbladder

George Everett Clark, Stillwater, Minn, Hahnemann Medical College and Hospital, Chicago, 1880, professor of theory and practice of medicine, University of Minnesota Medical School, Minneapolis, 1893-1905, formerly member of the state board of medical examiners, aged 83, died, August 26, of acute nephritis

William Edwin Leonard, Hadley, Mass, Hahnemann Medical College of Philadelphia, 1879, aged 80, for many years a member of the health department in Minneapolis, formerly on the staff of the Minneapolis General Hospital, died, August 28, in Minneapolis, of arteriosclerosis and coronary thrombosis

Kirby Gladstone Averitt ♂ Fayetteville, N C, Baltimore Medical College, 1893, member and past president of the state board of medical examiners, member of the county board of health, aged 65, on the staff of the Highsmith Hospital, where he died, September 18, of cerebral hemorrhage

Ollie H Parker, Custer, Okla, Fort Worth (Texas) School of Medicine, Medical Department of Fort Worth University, 1906, member of the Oklahoma State Medical Association, for six years health superintendent of Custer County, aged 62, died, July 12, of angina pectoris

Cornelius Joseph Buckley, Bedford, Mass, Albany (N Y) Medical College 1910, member of the New England Society of Psychiatry, for many years a member of the staff of the Veterans' Administration Facility, aged 59, died, August 31, of cerebral embolism

Jeanette Bacon Stubbs, Wilmington, Del, Howard University College of Medicine, Washington, D C, 1894, member of the board of health for ten years, formerly superintendent of the Babies Hospital, aged 66, died, September 30, of lobar pneumonia

Paul Raymond Williams ♂ Cape Girardeau, Mo, St. Louis University School of Medicine, 1912, served during the World War, aged 47, died, August 7, in St. Mary's Hospital, St. Louis, of peritonitis, following an operation on the colon

James William Cunningham ♂ Detroit, Detroit College of Medicine, 1901, aged 55, chief of the department of obstetrics, and secretary of the executive committee, St. Mary's Hospital, where he died, September 1, of myocarditis and uremia

Earnest Newton Scott, Hinsdale, Ill, Rush Medical College, Chicago, 1900, member of the Illinois State Medical Society, on the staff of the Hinsdale Sanitarium and Hospital, aged 59, died, August 31, of heart disease

Melton A McKenzie, Lake City, S C, Medical College of the State of South Carolina, Charleston, 1924, aged 38, died, September 30, in the Veterans' Administration Facility, Oteen, N C, of chronic pulmonary tuberculosis

Charles William Jackson, Monson, Mass, University of Vermont College of Medicine, Burlington, 1884, an Affiliate Fellow of the American Medical Association, aged 83, died, August 21, of senile gangrene

Thomas Coe Little, San Diego, Calif, John A. Creighton Medical College, Omaha 1896, member of the California Medical Association, aged 61, died, August 20, of coronary occlusion and arteriosclerosis

Churchill Allan Pritchard, Tivoli, N Y, Bellevue Hospital Medical College, New York, 1890, member of the Medical Society of the State of New York, aged 73, died, August 6, of cerebral hemorrhage

William Phillippe Bernard, Central Falls, R. I, Baltimore University School of Medicine, 1901, served during the World War, school physician in Central Falls, aged 62, died, September 2, of angina pectoris

William Newell Bailey ♂ East Liverpool, Ohio Miami Medical College, Cincinnati, 1878, on the staff of the East Liverpool City Hospital, aged 85, died, October 10, of pneumonia

George Howell Coffin, Longview, Wash, Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1904, aged 55, died in September of heart disease

Don Alvarado Bisbee, Bristol, Vt, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1876, also a druggist, aged 84, died, October 5, of acute myocarditis

Leo Rothenberg, San Francisco, University of California Medical School, San Francisco, 1933, aged 37, died August 30, in the Mount Zion Hospital, of stab wounds, self-inflicted

Gustave Christoph Hoefling, New York, Long Island College Hospital, Brooklyn, 1907, aged 48, died, September 11, in the Doctors Hospital, of carcinoma of the left tonsil

John Sears McCormack, Boston, Albany (N Y) Medical College, 1907, aged 52, died, August 23, in the Peter Bent Brigham Hospital, of bilateral bronchopneumonia

Harry Harold Thompson, Oxford, Neb, John A. Creighton Medical College, Omaha, 1909, aged 51, died, August 4, in a hospital at Holdrege, of cerebral hemorrhage

John L. Benepe, Anderson, Ind, Missouri Medical College, St. Louis, 1887, aged 70, died, September 28, in St. John's Hospital, of a streptococcal infection of the lung

Benjamin Franklin Rogers, Eastport, N Y, University of the City of New York Medical Department, 1886, aged 74, died, September 4, of carcinoma of the bladder

Jesse Strauss Heiman, New York, Syracuse University College of Medicine, 1904, aged 54, died, September 8, in the Park West Hospital, of coronary occlusion

Arthur Louis Cludas, Topeka, Kan, Keokuk (Iowa) Medical College, 1895, member of the Kansas Medical Society, aged 62, died, August 13, of arteriosclerosis

Charles Crittenden Brown, Tampa, Fla., Vanderbilt University School of Medicine, Nashville, Tenn, 1886, aged 78, died, August 20, of cardiorenal disease

Belle Scott Carmody, Boston, College of Physicians and Surgeons, Boston, 1923, aged 47, died, September 23, in the Boston City Hospital, of pneumonia

William Francis Ryan ♂ Utica, N Y, Syracuse University College of Medicine, 1932, aged 29, died, August 26, of acute pancreatitis and myocarditis

Newton Eno Richardson, Yuba City, Calif., College of Physicians and Surgeons of San Francisco, 1902, aged 57, died, August 10, of coronary occlusion

Raymond Kelly Baker, Eads, Tenn., Memphis Hospital Medical College, 1909, served during the World War, aged 49, died, August 19, of tuberculosis

William Douglas, Fairfax, Wash., University of Toronto Faculty of Medicine, 1895, aged 65, died, September 24, of angina pectoris and myocarditis

James Edmund Moses, Kansas City, Mo., University Medical College of Kansas City, 1885, aged 83, died, September 9, of bronchopneumonia

Thomas Jefferson Hackney, Lake City, Fla., College of Physicians and Surgeons, Baltimore, 1881, aged 77, died, suddenly, July 24, of heart disease

William McLure Reedy, Chio, S. C., Louisville (Ky.) Medical College, 1878, Confederate veteran, aged 89, died, August 21, of arteriosclerosis

Theodore H. Sedgwick, Pittsburgh, Jefferson Medical College of Philadelphia, 1877, aged 83, died, October 7, of acute pulmonary edema

Manasseh John Malament, Brooklyn, Long Island College Hospital, Brooklyn, 1898, aged 58, died, September 22, of coronary thrombosis

William H. Reynolds, Lexington, Ga., Atlanta Medical College, 1883, aged 74, died, July 31, of coronary disease with auricular fibrillation

John P. Sherrod, Port Gibson, Miss., Meharry Medical College, Nashville, Tenn., 1897, aged 69, died, August 13, of chronic myocarditis

Clarence Arthur Baldwin, Peru Ind., Homeopathic Medical College of Missouri, St. Louis, 1899, aged 64, died, October 9, of heart disease

Gustave Theodore Wieland, St. Louis, St. Louis College of Physicians and Surgeons, 1891, aged 67, died, September 9, of heart disease

Guy B. Dickson, Chicago, Hahnemann Medical College and Hospital, Chicago, 1886, aged 73, died, October 21, of heart disease

James C. Belsan, Chicago, Northwestern University Medical School, Chicago, 1905, aged 56, died, September 24, of myocarditis

Aghasie Oshana, Mason City, Iowa, Rush Medical College, Chicago, 1897, aged 67, died, August 23, of prostatic obstruction

George B. Hensley, Long Bottom, Ohio (licensed in Ohio in 1896), aged 80, died, August 19, of paralysis agitans and influenza

Alvin H. Bridgefarmer, Melissa, Texas (licensed in Texas under the Act of 1907), aged 62, died, August 25, of angina pectoris

John Long Basinger, Riceville, Tenn., Vanderbilt University School of Medicine, Nashville, 1890, aged 71, died, August 22

Edward Thomas Hoidge, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1902, aged 68, died, September 24

I. L. Anderson, Fort Smith, Ark., Gate City Medical College, Dallas, Texas, 1905, aged 78, died, July 30, of heart disease

Charles L. L. Cooper, Okolona, Ky., Louisville Medical College, 1887, aged 71, died, August 16, of coronary occlusion

Thomas Edgar Rogers, Waco, Ga., Atlanta Medical College, 1891, aged 75, died suddenly, July 25, of heart disease

Franklin H. Lyle, Boone, Iowa (licensed in Iowa in 1886), aged 86, died, August 9, in Des Moines of cerebral hemorrhage

Samuel M. Townsend, Madison Ind., Medical College of Ohio, Cincinnati, 1882, aged 88, died, August 27, of senility

Joseph Moorhead, New York, M. R. C. S. England, 1863, aged 93, died, September 19, of coronary thrombosis

James St. Clair Cussins, Decatur Ill., Rush Medical College, Chicago, 1877, aged 84, died, September 5

Theophilus Brenizer, Lamoni, Iowa (licensed in Iowa in 1886), aged 89, died, August 21, of general debility

Vance A. Vermillion, White Gate, Va., Maryland Medical College, Baltimore, 1900, aged 57, died, August 31

James H. Stroud, Cartersville, Ga., Atlanta Medical College, 1888, aged 69, died, August 19

Charles D. Jones, Moline, Ill., Chicago Medical College, 1877, aged 85, died, September 9

Correspondence

CONTRACEPTION

To the Editor—THE JOURNAL is to be congratulated as well as Dr. Latz for his statement "Economic conditions or other weighty reasons may put couples in a position in which they need to limit their offspring" (THE JOURNAL, October 19, p. 1241). Many of us who are engaged in active contraceptive practice have been preaching this for years. We dared not express ourselves so openly on the question of economic needs because of legal restrictions but rather stressed frank medical indications. The depression did for us what we dared not suggest ourselves.

I am not going to take issue with the "safety" of the safe period or discuss its shortcomings in this communication. Others as well as I are collecting records pointing out the large percentage of failures, and time plus pregnant women will determine its fate as a practical birth control measure. The study of the so-called safe period is intriguing, but its clinical application is far too premature and questionable to advocate it to anxious, worried, often sick women.

THE JOURNAL recently published an article with photographs showing the dangers of gold stem pessaries (Sussex, L. T. Penetration of the Uterus by Gold Stem Pessary, THE JOURNAL, May 13, 1933, p. 1490). In my opinion a great opportunity was missed at that time in not advising physicians in the use of safe, scientific and effective contraception. Whether the condom, vaginal rubber occlusive diaphragm, douche, suppository, jelly or cream is used as a contraceptive measure, the physician should learn of the relative efficiency and shortcomings of these methods through his accredited journal rather than rely for his information on the advice of commercial advertisers and detail men. Despite the fact that many studies on the relative values of contraceptive devices have been made, THE JOURNAL has not deemed it advisable to publish any of them.

MARIE PICHEL WARNER, M.D.,
Bronx, New York City

COMMENT—At the request of the House of Delegates, the Board of Trustees has appointed a committee to investigate scientifically the various methods of contraception. The report of this committee will be made to the House of Delegates at the next annual session.—ED

MALARIA IN A VILLAGE

To the Editor—The editorial comment on malaria in a village (THE JOURNAL, August 17, p. 517) is of more than passing interest to me, not so much that such outbreaks as reported may be so rare, but on account of the character of the epidemiologic warning offered.

I assume that the purpose of Current Comment is to inform the scientific readers of THE JOURNAL (local health authorities or physicians) of the dangers from malaria transmission through the medium of the traveling public. Please permit a quotation from the article. There are many other communities in the United States which are similarly in danger of an outbreak of malaria. When a malaria infected person visits these communities the stage will be set for an outbreak of malaria. Perhaps a stop in town just long enough to have lunch or to take on motor supplies would be sufficient for the mosquitoes to find the malaria-infected visitor. For such of your readers as do not know that *Anopheles quadrimaculatus* (our principal malaria vector) practically never bites in the daytime and that the other proved vectors of this genus are essentially night biters, would it not have been more valuable for you to tell your readers of the real dangers of introduction of malaria by overnight stops by "carriers" in

Anopheles-infested camps, hotels, tourist homes and the like? Why not allow the tourist to eat his "lunch" in peace and secure his "motor supplies" without fear and trembling lest he endanger the villagers?

T H D GRIFFITTS, M D, Jacksonville, Fla

METHYLENE BLUE IN CYANIDE INTOXICATION

To the Editor—An editorial published in THE JOURNAL, August 31, page 721, comments on Wendel's paper regarding the much discussed question of the mechanism of methylene blue antidotic action in cyanide intoxication, in which the author proves that it is due to the formation of methemoglobin.

The results of experiments published in 1933 (*Rev Soc argentina de biologia* 9 461, 1933, *Compt rend Soc de biol* 114 947, 1933) had already permitted me to arrive at the same conclusion. Methylene blue was injected into dogs and methemoglobin was determined at different intervals following the injection by means of van Slyke's gasometric method. Not more than 17 per cent of the total hemoglobin was transformed into methemoglobin. On the other hand, sodium nitrite in adequate doses transforms into methemoglobin more than 60 per cent of the hemoglobin in the circulating blood. This explains the higher antidotic power of sodium nitrite in cyanide intoxication, which I had already demonstrated, and has been successfully applied in combination with sodium thiosulphate in several cases of cyanide intoxication in man.

ENRIQUE HUG, Rosario, Argentina

OWNERSHIP OF X-RAY FILMS

To the Editor—Your editorials on the ownership of roentgenographic negatives and particularly the last (October 12) are very encouraging to those who perform roentgen examinations. Each new decision confirming the fact that the films belong to the physician who produces them aids the cause of science and the actual practice of medicine for, other things being equal, the physician who keeps his films and reviews them from time to time is presumably better equipped professionally than the one who does not retain them for further study.

Until proper decisions have been handed down by the courts in every state and the matter is no longer a subject for debate it might be helpful for all physicians who practice diagnostic roentgenology to adopt some specific form of statement on their appointment slips such as that which has been used in my office for the past twelve years and which reads as follows:

NOTE—It is understood that the original films resulting from x-ray examination are to be retained and permanently filed for study by Dr. Kantor. Patients are entitled to detailed reports or to prints of original negatives at nominal cost if they so desire.

This effectively settles the ownership question in advance of the examination and thus prevents any misunderstanding.

JOHN L. KANTOR, M D New York

RESUSCITATION

To the Editor—I have recently received several letters from men and organizations interested in resuscitation from drowning, electric shock, and carbon monoxide asphyxia. These letters ask whether any of the modifications of the Schafer prone pressure method recently proposed afford any real advantage over the procedure now in use by the American Red Cross, Boy Scouts and rescue crews of city police and fire departments.

In my opinion, the answer is positively No!

The Schafer method has been standardized by an immense experience. It has been taught, it is estimated, to more than

thirteen million men and boys, as well as many women and girls. It is saving many lives each year, particularly from drowning. It would be unfortunate if uncertainty and dispute over details were introduced for no real advantage.

All forms of manual artificial respiration are essentially expiratory in effect. The inspirations are wholly due to the tonus and elasticity of the respiratory muscles of the victim. The operator cannot increase the volume of the inspirations by any manual method.

These statements, however, do not justify the use of artificial respiration apparatus of the pulmotor type, for when manual artificial respiration ceases to be effective, the body has entirely lost its tonus, and the victim is irrecoverably dead.

YANDELL HENDERSON, PH D, New Haven, Conn.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

VACCINES AGAINST POLIOMYELITIS—KRUEGER VACCINE FOR PERTUSSIS

To the Editor—May I have information on the following: 1 The Brodie-Park vaccine for vaccination against acute anterior poliomyelitis, with references to the literature its comparison with Dr J. A. Kolmer's vaccine against this disease where the vaccine can be obtained dosage and duration of immunity. 2 Krueger's vaccine for the treatment of acute cases of whooping cough its composition dosage, where obtained and value. M D New Jersey

ANSWER—1 Brodie's vaccine consists of a 10 per cent suspension of formaldehyde treated virus. The vaccine is administered intradermally and subcutaneously in one or two 5 cc. doses. A recent communication from Brodie states that more than 6,000 children have been vaccinated without untoward effects. The disease did not appear in any vaccinated child, although complete data for the controlled experiments are not yet available.

Kolmer's vaccine differs from Brodie's in that it is an attenuated virus, consisting of a 4 per cent suspension of monkey spinal cord in a 1 per cent sterile sodium ricinoleate solution. Kolmer administers his vaccine subcutaneously in three divided doses, which vary with the age of the child. More than 6,000 children have been vaccinated, but a finished analysis has not yet been made.

The vaccine may be obtained directly from both Brodie and Kolmer. The Merrell Company of Cincinnati is also supplying the latter vaccine.

The work has not been followed for a sufficient length of time to ascertain the duration of immunity, although monkeys vaccinated by Kolmer have now retained their immunity for three years. Following are references:

- Brodie Maurice *J Exper Med* 56 493 (Oct) 1932
- Brodie Maurice *Science* 70: 594 (June 29) 1934
- Brodie Maurice *Proc Soc Exper Biol & Med* 32: 300 (Nov) 1934
- Park W H *Pediatric Magazine* May 1935
- Kolmer J A and Rule, Anna M *J Immunol* 26 505 (June) 1934
- Kolmer J A and Rule Anna M *Am J M Sc* 188 510 (Oct) 1934
- Kolmer J A Klugh G F Jr and Rule Anna M *A Successful Method for Vaccination Against Acute Anterior Poliomyelitis* THE JOURNAL Feb 9 1935 p 456

2 Krueger's vaccine for pertussis is an undenatured antigen prepared by mechanical disruption of the washed *Haemophilus pertussis* by grinding in a special mill with stainless steel balls and then filtering. The therapeutic dose recommended has been from 0.5 to 2 cc, depending on the severity of the illness. This dose is repeated daily if necessary. It may be obtained from Eli Lilly & Co.

Reports by Stallings and Nichols indicate a beneficial effect from such therapy in about 90 per cent of patients. Physicians using this antigen have been favorably impressed with the clinical results. However, there has not been any general acceptance of this therapy, because of the lack of sufficiently controlled studies. None of these preparations stand accepted by the Council on Pharmacy and Chemistry.

SYPHILIS AND PREGNANCY

To the Editor—A woman, aged 25 married seven years has been in perfect health all her life and physical examination at the present time including a neurologic examination is negative. In January 1930 she was delivered of a baby girl who died three months later in Baby's Hospital New York. The Wassermann reaction of the baby and of the mother was 4 plus. The father's was negative. The patient has four sisters and two brothers living and well. One sister died at the age of 1 year of inflammation of the bowels (?) and one brother died at the age of 4 years of acute indigestion (?) according to the patient's story. The patient's mother has had several stillbirths. One sister has a positive Wassermann reaction and another has a negative one. The rest of the brothers and sisters and parents are indifferent and will not submit to a blood test. The patient's mother and father are about 60 years of age and in apparently good health. My patient has had four courses of neosarsphenamine of 3 Gm each twenty four injections altogether. Her blood Wassermann reaction was 4 plus-4 plus and is now 2 plus-4 plus and the local physician in charge of the venereal disease clinic believes that there is no use in giving her any more. She had her first course in 1930 and the last in 1932. She has not had a spinal puncture. The questions I should like answered are 1 Will more treatments be of benefit to her? 2 Would you consider this a case of congenital syphilis? 3 Would you advise her to have another child which she wants? 4 Could the positive Wassermann reaction be caused by anything else occurring in two members of the same family? 5 What are the dangers to the husband? 6 What future health can you guarantee such a patient? If this is published please omit name

MD New York.

ANSWER.—No mention is made of the administration of preparations of the heavy metals, such as mercury and bismuth, hence it is assumed that none of these were given. The persistence of the positive Wassermann reaction may be due to the omission of mercury and bismuth compounds in the treatment. A spinal puncture should certainly be made and, if the spinal fluid Wassermann test is positive, intensive treatment is surely indicated.

1 Even if the spinal fluid Wassermann test should prove negative, the patient should receive several courses of treatment with compounds of mercury and bismuth.

2 No proof is given in the history that this is a case of congenital syphilis. Neither the sister's positive Wassermann reaction nor the mother's stillbirths necessarily point to the fact that the patient has congenital syphilis. It is almost certain that this is a case of an acquired infection.

3 The patient should not become pregnant until repeated Wassermann tests have been negative for at least one year, preferably longer. Should the patient become pregnant after the Wassermann test has remained negative for a time, more treatment should be carried out during the pregnancy.

4 Aside from such conditions as yaws, which is rare in this country, repeated positive Wassermann reactions definitely indicate the presence of syphilis. There is no reason why two sisters should not have acquired syphilis.

5 Since the patient has had syphilis for at least five and a half years, the chances of infecting the husband at this time are slight. The older the syphilitic infection, the less likelihood there is of infecting the mate. However, repeated Wassermann tests should be made of the husband's blood and also at least one serologic test of his spinal fluid.

6 With intensive and if necessary repeated courses of therapy, the outlook for this patient's health is good but it is hazardous to "guarantee" anything in medicine.

ARGYRIA

To the Editor—I would appreciate your writing me the minimum amount of silver nitrate used as a douche solution and as bladder irrigation that has produced argyria also the length of time that it takes for the blueness of the skin to develop to the maximum. A woman whom I have been treating for gonorrhea has begun to develop a sort of faint slate color of the skin of the face. She frequently has a slight fever. She may have Addison's disease but the classic symptoms are all present. In my irrigating solutions of the bladder and vagina cervix I have estimated that 42 grains (2.7 Gm.) of silver has been used in the treatments. Of course this silver has not all been retained as only the wet condition of the tissues have been retained after she left the office each time.

F C NEBBIT MD Atlanta Ga

ANSWER.—It is generally known that argyria follows the prolonged administration of silver nitrate or the use of silver salts.

Davidson (*J Cutan Dis* 34 605 [Aug] 1916) reported a case of generalized argyria in a patient who had acute gonorrhea. Discoloration of the hands commenced in three weeks and attained the bluish color in six weeks. He used urethral injection, three times a day, retaining the solution for five minutes. Prior to coming under observation, as far as could be determined, the following amounts were used: mild silver protein 4 ounces (120 cc.) at 10 per cent 2 ounces (60 cc.) 25 per cent, 2 ounces at 30 per cent strong silver protein 4 ounces

at 10 per cent, albargin 4 ounces at 5 per cent. The author further states that, up to the time of the first appearance of discoloration 800 grains (52 Gm.) of mild silver protein and 200 grains (13 Gm.) of strong silver protein were used.

Sollmann (*Manual of Pharmacology*, 1932, p 1048) states that argyria develops gradually after prolonged internal or external use of silver nitrate or salts when the total dose has reached from 15 to 30 Gm.

Sutton (*Diseases of the Skin*, 1931, pp 612-613) states that Stillman and Lawless have successfully employed a local intradermal injection of a mixture of 1 per cent potassium ferri-cyanide with 6 per cent sodium thiosulphate.

ULCERATED AREA ON WRIST

To the Editor—A white woman aged 25 single had a ganglion removed from the tendons on the extensor aspect of the left wrist in July 1932. A severe and extensive infection followed. Slowly the acute inflammation subsided and a small chronic ulcer remained. The wrist and to a lesser extent the fingers became immobile in extension. A biopsy of the edge of the ulcer was made and although I do not know the report I believe it was negative. The Wassermann reaction is negative. The skin tuberculin is positive but complement fixation for tuberculosis and roentgen examination of the chest are negative. The patient is restless and worries and has lost some weight. She is not well nourished but I can find no evidence of disease except for the ulcer. She has had radium which she says made it larger, and ultraviolet rays which did not improve it. She still has a very slight and low grade infection in and around the tendon sheaths and the granulations look very unhealthy. I believe that proper orthopedic and plastic surgery could restore normal use to the wrist and heal the ulcer. If you can guide me in the treatment or recommend some men who you think might be able to take care of it you will be helping me and the patient. I might say that she has seen many physicians and surgeons nearby and she is no better. The urine is normal. The fasting blood sugar was 71 mg per hundred cubic centimeters. Please omit name

MD New York.

ANSWER.—This case suggests several possibilities one, that the original condition was not a simple ganglion but a tuberculous process. Tuberculous tenosynovitis is not infrequently diagnosed as ganglion, and because the process is not completely eradicated recurrences following an operation are rather frequent. Another possibility is that the patient received excessive radiation treatment at the site of the ulcer and that as a result the blood supply to the tissues has been so greatly diminished that spontaneous healing is impossible.

The plan of treatment most likely to be successful is, first, cleaning up of the ulcerated area by careful aseptic treatment for from seven to ten days, second, after the infection has been cleared up as well as possible, complete excision of the infected area and covering of the raw surface with a pedunculated flap from the abdomen or thigh, third, if complete excision of the involved area requires excision of essential tendons, or if such tendons have already been destroyed tendon repair, which should be carried out at a later time. This last step, of course, would have to be postponed until the transplanted flap of skin and subcutaneous tissue has been soundly healed for several months.

DERMATITIS FROM SKIN FOOD

To the Editor—A woman came to my office with a swelling puffiness and redness on both cheeks especially under the eyes. She stated that she bought a skin food which she applied to her face. The next morning the swelling appeared. I eliminated all local and constitutional diseases for the possible causes of the swelling and prescribed a soothing lotion (calamine lotion). The swelling disappeared in three days with scaling of the skin. I therefore attributed this condition to the skin food. The ointment that she applied trades under the name Duharry Special Skin Food manufactured by the Hudnut Sales Company. The formula which was sent to me contains the following ingredients

| | per cent |
|-----------------------------|----------|
| Lanolin anhydrous U S P | 36 4 |
| Spermaceti U S P | 6 4 |
| Snow white petrolatum U S P | 48 2 |
| Distilled water | 7 875 |
| Perfume oils | 1 125 |

The company claims that it would be impossible for any of the ingredients to produce the irritation. I attribute the condition to the patient's idiosyncrasy to perfumed oil. Will you kindly advise me whether the other ingredients might have produced the irritation?

ISRAEL BRIDDER MD Philadelphia

ANSWER.—It is entirely possible that any one or more of the ingredients of this "skin food" except of course distilled water, might have been responsible for the dermatitis. Patch tests should be made by applying a small amount of each ingredient under oiled paper, oiled silk or gutta percha and fastened to the skin with adhesive plaster. These tests should be made on apparently normal skin and should be examined after forty-eight hours unless itching occurs earlier. A control with the covering substance should be made, though irri-

tation due to it or to the adhesive plaster can usually be easily distinguished from that due to the material tested

The inquirer is correct in suspecting the perfumes. Hypersensitivity to perfumes is not uncommon, much less so than hypersensitivity to the other ingredients

SYPHILITIC PHLEBITIS

To the Editor—A Negro, aged 18 awoke with an aching pain in the right thigh in the region of the femoral triangle April 12 this was associated with tenderness in the same region, and with a low backache. No other symptoms have been present. The past history is negative except for a penile sore clinically strongly resembling a chancre just one year ago at which time the blood Wassermann reaction was 3 plus Eagle positive. No treatment was given. He has never had a penile discharge. In October 1934 the Wassermann and Eagle tests were negative. The social and family histories are without significance. Physical examination on the third day of the illness showed him moderately ill. The temperature was 101.4 F. There were scattered acneiform lesions on the shoulders and back. There were several large thin, atrophic scars on the legs. There was a dirotic pulse which usually is proportional in rate to the temperature. An old scar was present on the shaft of the penis. There was palpable thickening of the superficial veins of both thighs and, to a less extent of both forearms and cubital regions. Tenderness was shown in the right femoral triangle. Palpable but not tender inguinal lymph nodes were present on both sides. Pulsations in the dorsalis pedis and posterior tibial arteries were felt with difficulty on the right, and not at all on the left. There has been no edema. During observation, the temperature was remittent with daily peaks of 101 to 103.8 F for thirteen days and then a gradual fall followed by another elevation of temperature which was associated with a shift of the tenderness and pain to the left femoral region and notable extension of the palpable process in the veins down the legs to the feet. After the twenty fourth day the temperature sought normal levels and remained so. The laboratory work showed a normal urine unaltered red blood cell count and hemoglobin moderate leukocytosis (15 350 with 80 per cent polymorphonuclears) negative Widal and negative Wassermann and Eagle tests on two specimens. A biopsy of a superficial vein of the right thigh showed great thickening and fibrosis of the wall the lumen being very small and with widespread vacuolization apparently lipid in nature in the wall of the vein. What are the diagnostic possibilities and probabilities and the treatment in this case of diffuse and multiple involvement of the veins? Kindly omit name

M D, Texas

ANSWER—Acute syphilitic phlebitis is a relatively infrequent complication of early secondary syphilis. It manifests itself as an inflammatory process involving the whole or several segments of the superficial veins of the lower extremities, most frequently the internal saphenous vein. The veins may be palpated as indurated cords or there may be nodules attached to the superficial veins of the hypoderm, and there may be moderate edema and redness of the skin overlying the vein. The process tends to be multiple, progressing from one vein to another and tending to recur in the same vein or in another limb. The symptoms may be slight or severe, causing nocturnal pains, moderate leukocytosis and a slight rise of temperature. Involution with antisyphilitic therapy takes place in from two to four weeks, leaving indurated cords after the acute reaction has subsided. In some cases the lesions simulate erythema nodosum. Pathologically the main change is a proliferation of the connective tissue in the subendothelial layer, causing the endothelium to protrude into the lumen of the vein in the form of buds. The main points of distinction from the phlebitis of other infectious processes are the lack of constitutional and local symptoms, the multiplicity of the veins involved, the marked tendency to recurrence, the lack of formation of an embolus, and the prompt response to antisyphilitic therapy. In the correspondent's case the negative Wassermann reaction, the rather indefinite history of syphilis and the high temperature speak against the diagnosis of an acute syphilitic phlebitis and rather in favor of an infectious phlebitis. Nevertheless the patient should be given the benefit of antisyphilitic therapy and serologic tests should be made at intervals.

EPINEPHRINE AND MYOCARDIAL DISEASE

To the Editor—In an article by Dr. Paul A. Davis in THE JOURNAL, Sept. 29 1934 page 965 the statement is made that epinephrine should not be used in cases of carbon tetrachloride poisoning if there is a possibility of any myocardial involvement. Will you please be good enough to comment on this statement, indicating in what lies the rationale of it?

N I ARDAN M D Niagara Falls, N Y

ANSWER—When considering the use of epinephrine in myocardial disease, there are a number of factors to be considered. Its action from moderate doses may be summarized as follows.

Action on the heart 1 An increased heart rate is a characteristic feature, but it may cause a slow, full beat characteristic of inhibitory activity.

2 It causes a more complete contraction of the heart, but, if there is great acceleration of the heart, relaxation may not be complete and the output of the heart may be decreased.

3 There is an increased irritability of the heart and thus a predisposition to ectopic beats and auricular or ventricular fibrillation.

4 The reports on the effect on the coronary vessels are conflicting but apparently dependent on the dose, certain doses producing dilatation and other doses producing constriction.

Action on the peripheral vessels It produces a vasoconstriction of the peripheral vessels. The splanchnic vessels are constricted most, the limb vessels less and the pulmonary and cranial vessels least, leading to an increased peripheral resistance and increased burden to the heart.

Epinephrine increases the irritability of the heart muscle. In myocardial disease, epinephrine would be contraindicated because of its tendency to induce ectopic beats in either the auricle or the ventricle and to induce auricular or ventricular fibrillation.

In myocardial disease with failure or a very low cardiac reserve associated with shock, epinephrine is contraindicated because it produces an increased peripheral resistance with increased work for the heart.

In direct answer to the question, one must consider the cause, type and severity of the myocardial disease before giving epinephrine. In the mild degrees of myocardial disease with little or no increased irritability of the heart, epinephrine can probably be used with safety. On the other hand, one wonders why it should be used at all in shock. Its action on the cardiac vascular system is of very short duration, and the possibilities of doing more harm than good with this drug must be considered.

GONORRHEAL INVOLVEMENT OF JOINTS

To the Editor—What is the accepted treatment of an acute gonorrheal involvement of the elbow joint? In case one immobilizes the parts, what are the criteria as to the proper duration of immobilization? What is the status of protein therapy in acute gonorrheal arthritis?

J PHILLIPS EDMUNDSON M D Kansas City Mo.

ANSWER—There are two schools of opinion in regard to the treatment of infection of the elbow joint (1) short period of immobilization, and (2) no immobilization.

Some authorities feel that immobilization predisposes to ankylosis. There are, however, just as many and as good authorities who believe that the surest way to prevent ankylosis is to immobilize for a very short period until the active hypersensitive stage is passed.

The position of immobilization should be midflexion of the elbow and midsupination of the forearm with slight dorsiflexion of the wrist.

Following this short immobilization period, physical therapy should be instituted, especially mild active movements followed by very gentle passive movements. Diathermy may be of value but, although short wave diathermy has been used, no statistics are available as yet.

The treatment of the primary lesion is important.

The inquirer should note the most recent work on hyperpyrexia, which in a small number of carefully checked cases has resulted in complete cure, in as few as a number as four treatments. This includes raising the temperature to 106, 107 or 108 F over a period of hours.

USE OF WHEY IN HYPERTENSION

To the Editor—What is the usefulness of evaporated whey taken in tablespoonful doses two or three times daily as a treatment of arterial hypertension? Will you please discuss this and give name of source of supply of this product? EDWARD S PARKER M.D., Ida Grove, Iowa.

ANSWER—Whey powder, containing the solutes of milk, has been used recently in the therapy of hypertensive arterial disease. The number of remedies, diets and other measures suggested for the treatment of hypertension is legion. This is a priori evidence that none of these innumerable methods of management are wholly satisfactory. The evaluation of any therapeutic measure in hypertensive disease is extremely difficult, transient reduction of the arterial tension alone is not a criterion of satisfactory result. Thus far the clinical trial of evaporated whey is entirely inadequate for drawing any conclusions as to the value of the measure. A great many patients must be observed over a long period, at least one year, before conclusions are warranted.

The chief constituents of evaporated whey are lactose (about 70 per cent) and the electrolytic salts of milk, including considerable calcium. Calcium salts in large doses have been extensively used in the management of hypertensive disease and the past, the therapeutic results have proved disappointing and even the more enthusiastic advocates of such calcium therapy have come to admit its futility. It is suggested that 2 ounces (60 Gm) of whey powder a day changes the intestinal flora

and has a mild laxative effect by inducing lactic acid fermentation in the bowel. However, there is no convincing evidence that so-called intestinal toxemia has any etiologic significance whatever in hypertensive disease. Alvarez has shown that constipation is more frequently associated with hypotension than with hypertension.

It is highly questionable whether such therapy will fulfil the expectations of its sponsors, one must keep an open mind and refuse to judge until much more evidence has been accumulated and analyzed.

DIABETES INSIPIDUS

To the Editor—A woman about 25 years of age developed symptoms of extreme thirst and polyuria during her second pregnancy. The urine output averaged 4 and 5 quarts (liters) a day. She was obliged to drink the required amount of water both night and day. The specific gravity averaged 1.010. After delivery the symptoms persisted for two or three months as at first but after this period though still troubled with the frequent urination, she was able to get sleep during the night. The same amount of urine is still eliminated during the twenty-four hours as formerly. Would this be considered diabetes insipidus or is it some upset of the pituitary due to pregnancy? What if any treatment is indicated?

LOUIS L. SHERMAN, M.D., Oakland Calif

ANSWER—In the absence of hyperglycemia and glycosuria, the diagnosis of diabetes insipidus seems most probable. Administration of various preparations of the posterior pituitary gland have been successfully used in controlling this condition. Probably the simplest and least expensive method of administration is to apply desiccated powdered posterior pituitary gland to the nasal mucosa with the finger tip. The amount used depends on the severity of the case but may be little e.g., 5 mg. two or three times daily (Vidgoff, Ben Posterior Pituitary Therapy in Diabetes Insipidus, *Endocrinology* 16:289 [May-June] 1932).

HEMOSTASIS IN LACERATION

To the Editor—Can you advise me as to the best and quickest hemostatic agent to be used in fresh lacerations? I frequently have occasion to take care of boxers who have received facial lacerations. The preparations used by their managers between rounds to stop the bleeding render the wounds unfit for primary closure. Monsel's powder is the most commonly used chemical, and I have been unable to clean the wound following its use without an extensive débridement. Please omit name.

M.D., California

ANSWER—Application of solution of epinephrine with compression, or the flooding of the wound with solution of hydrogen dioxide followed by compression stops hemorrhages without damaging the tissue. Following either of these, or, if the bleeding is not profuse, even without the preliminary use of these agents, finely powdered sugar applied with pressure is probably as good and harmless as any hemostatic that can be found.

LIME JUICE NOT A RELIABLE PROPHYLACTIC FOR OPHTHALMIA NEONATORUM

To the Editor—Kindly answer the following question. In a book on "mothercraft" written by a French physician in one of the languages of the African Congo the use of fresh lime juice is recommended in the prophylaxis of ophthalmia neonatorum when a solution of silver nitrate for the Crédé method is not available. Is there scientific justification for this treatment?

ELLEANOR TAYLOR CALVERLEY M.D. Hartford Conn

ANSWER—There is no mention in the literature of the use of lime juice as a substitute for silver nitrate as a prophylactic agent against ophthalmia neonatorum. It is conceivable that the instillation of lime juice into the conjunctival sac is so irritating that an excessive flow of tears results thereby washing infectious material away and thus preventing the development of the disease in a small percentage of cases.

BOWLEGS

To the Editor—What treatment if any is there for bowlegs in a healthy child of 6 months?

R. F. SHEETS M.D. Carthage Ill

ANSWER—1. The correspondent should have submitted (1) a photograph of the child's legs, (2) a statement of whether the deformity is increasing, decreasing or stationary, (3) a statement of whether there is any hereditary or familial history, (4) the place of birth, (5) roentgenograms to determine whether thickening of the cortex is on the concave or convex side of the bone.

There are no guideposts to tell the physician which legs will or will not correct themselves. Nature is kind to most children but a goodly number of deformities do not take care of themselves.

The proper treatment is a plaster-of-paris cast or a series of casts which may be "wedged." After the correction is obtained, braces may be applied. Massage and binding of the legs together will hasten correction in mild cases. Cod liver oil, ultraviolet rays, viosterol and other preparations including proper food aid in the correction of this type of deformity.

STROPHANTHUS IN CORONARY DISEASE

To the Editor—I recently read an article in some journal quoting the statement of some authority regarding the use of strophanthus in the treatment of angina and coronary disease. Having been diagnosed as having a coronary sclerosis I was rather interested in this treatment but am unable to locate its source. I will appreciate it if you can advise me where I can get full details of this treatment and its results. Please omit name and address.

M.D. South Dakota

ANSWER—Neither digitalis nor strophanthus should be used as a routine procedure in the treatment of coronary disease per se. If auricular fibrillation is present, digitalis should be used in its control, if necessary. This is the only real indication for its use in such cases. All the drugs of the digitalis series, of which strophanthus is one, show evidence of a vasoconstrictor action and are contraindicated in coronary disease. They also increase irritability of the heart muscle, another contraindication.

COMPOSITION OF CERUMEN

To the Editor—I would appreciate an analysis of the constituents of cerumen from the human ear. Please omit name.

M.D., Lebanon Pa.

ANSWER—Following is the composition of dried cerumen as quoted by Creed and Negus in the *Journal of Laryngology and Otology* (April 1926) from the work of Lannois and Martz.

| Principal Constituents | Moist | Dried in Vacuo |
|-----------------------------------|-------|----------------|
| Water | 56.53 | |
| Free fatty acids | 1.30 | 2.99 |
| Fats | 3.55 | 8.16 |
| Cholesterolin | 3.07 | 7.06 |
| Soluble in alcohol | 7.0 | 16.10 |
| Urea | 0.20 | 0.46 |
| Soluble in cold and boiling water | 11.29 | 25.96 |
| Insoluble | 14.40 | 33.12 |
| Various substances | 2.66 | 6.15 |
| | 100.0 | 100.0 |
| Total nitrogen | 2.7 | 6.21 |
| Ash | 3.08 | 7.08 |
| Total insoluble fatty acids | 8.63 | 19.84 |
| Lecithin | 1.63 | 3.74 |

VISION IN INFANT'S EYE

To the Editor—A statement was made that an infant perceives objects as inverted images. Does an infant or a newly born lower animal acquire the ability to project an inverted image into an erect image?

MARTIN J. TREICHLER M.D., Bartlett, Ill

ANSWER—It is true that any image on the retina, whether in the eye of a new-born or of an adult, is inverted. This is discussed at length in Helmholtz's *Physiological Optics*, volume 1, page 91. But in the projection of that image on the cerebral cortex through the optic pathways it is probable that an inversion occurs. If this is the case, the image in the new-born eye is projected cortically in just as upright a position as in the adult eye. The character of vision that results after the removal of a complete congenital bilateral cataract justifies that assumption.

DANGERS OF TETRAETHYL LEAD

To the Editor—I have a patient working in tetra-ethyl lead at a gasoline refinery who has been suffering with painless hematuria for two weeks. Preliminary cystoscopy reveals a marked engorgement of the bladder trigon. Pending further cystoscopic study could you inform me whether tetra-ethyl lead may be a causative factor? Please omit name.

M.D. Pennsylvania

ANSWER—So protean are the manifestations of the action of lead on the human body that it is conceivable that a trigonitis might be attributed to this cause. Practically, however, this concept is not tenable, particularly in the absence of other and more characteristic features of plumbism. On the other hand, gasoline into which tetra-ethyl lead apparently was introduced is a more likely source of bladder irritation. On the assumption that the disorder described is to be associated with work as a cause and not to work-extrinsic causes, it is believable that the gasoline (benzine, naphtha) is a more probable cause than tetra-ethyl lead. Frequent urination and bladder discomfort are clearly associated with the action of hydrocarbon solvents. Occasionally when large wounds are freely cleansed with such solvents as benzene or solvent naphtha a mild hematuria appears within the next twenty-four hours.

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Written examination for Group B applicants will be held in various cities throughout the country, March 14. Oral examination for Group A and B applicants will be held in Kansas City Mo. May 11-12. Applications for written examination should be filed with the secretary before Jan 15. Sec. Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada Dec. 7. Sec. Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY St. Louis Nov. 18. Asst. Sec. Dr. Thomas D. Allen, 122 S. Michigan Ave., Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St. Louis, Jan. Sec. Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY Kansas City, Mo. May 9. Sec. Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS St. Louis Nov. 20. Sec. Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY New York Dec. 30. Sec. Dr. Walter Freeman, 1726 Eye St. N. W., Washington D. C.

AMERICAN BOARD OF RADIOLOGY Detroit Dec. 12. Sec. Dr. Byrl R. Kirklm, Mayo Clinic, Rochester, Minn.

ARIZONA Basic Science Tucson, Dec. 17. Sec. Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson.

ARKANSAS Medical (Regular) Little Rock, Nov. 12. Sec. State Medical Board of the Arkansas Medical Society, Dr. A. S. Buchanan, Prescott, Medical (Eclectic), Little Rock, Nov. 12. Sec. Dr. Clarence H. Young, 207½ Main Street, Little Rock.

CALIFORNIA Reciprocity Los Angeles Dec. 4. Sec. Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT Medical (Regular) Hartford Nov. 12-13. Endorsement Hartford Nov. 26. Sec. Dr. Thomas P. Murdock, 147 W. Main St., Meriden, Medical (Homeopathic), Derby Nov. 12. Sec. Dr. Joseph H. Evans, 1488 Chapel Street, New Haven.

FLORIDA Tampa Nov. 11-12. Sec. Dr. William M. Rowlett, Box 786, Tampa.

KANSAS Topeka Dec. 10-11. Sec. Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.

KENTUCKY Louisville, Dec. 3. Sec. Department of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.

MAINE Portland Nov. 12-13. Sec. Board of Registration of Medicine, Dr. Adam P. Leighton Jr., 192 State St., Portland.

MARYLAND Medical (Regular) Baltimore Dec. 10-13. Sec. Dr. John T. O'Mara, 1211 Cathedral St., Baltimore. Medical (Homeopathic), Baltimore, Dec. 10-11. Sec. Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS Boston Nov. 12-14. Sec. Board of Registration in Medicine, Dr. Stephen Rushmore, 413 State House, Boston.

NEBRASKA Lincoln Nov. 19-20. Dir. Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NORTH CAROLINA Endorsement Raleigh Dec. 9. Sec. Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.

OHIO Columbus Dec. 3-5. Sec. State Medical Board, Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA Oklahoma City Dec. 11. Sec. Dr. James D. Osborn Jr., Frederick.

OREGON Basic Science Portland Nov. 16. Sec. Mr. Charles D. Byrne, University of Oregon, Eugene.

SOUTH CAROLINA Columbia Nov. 12. Sec. Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

TEXAS Houston, Nov. 18-20. Sec. Dr. T. J. Crowe, 918 Mercantile Building, Dallas.

VIRGINIA Richmond Dec. 11-13. Sec. Dr. J. W. Preston, 28½ Franklin Rd., Roanoke.

WISCONSIN Basic Science Milwaukee Dec. 21. Sec. Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

Washington July Examination

Mr. Harry C. Huse, director, Department of Licenses, reports the written examination held at Seattle, July 15-17, 1935. The examination covered 7 subjects and included 70 questions. Twenty-six candidates were examined, all of whom passed. Twenty-one physicians were licensed by reciprocity and 9 physicians were licensed by endorsement. The following schools were represented:

| School | PASSED | Year Grad | Number Passed |
|---|----------------------|-----------|---------------|
| University of Colorado School of Medicine | (1934)* | | 1 |
| Northwestern University Medical School | (1930) | (1932)* | 5 |

Child Psychiatry By Leo Kanner M.D. Associate Professor of Psychiatry the Johns Hopkins University Baltimore With prefaces by Adolf Meyer M.D. LL.D. Henry Phipps Professor of Psychiatry the Johns Hopkins University Baltimore and Edwards A. Park M.D. Professor of Pediatrics the Johns Hopkins University Baltimore Cloth Price \$6 Pp 527 Springfield Illinois & Baltimore Charles C Thomas 1935

Dr Kanner attempts to write "the first text book of child psychiatry in the English language." The author states that he attempts to cover the entire field of children's personality disorders on a broad objective, unbiased and practical basis. Although no previous formal textbook has been written concerning the psychiatric disorders in childhood, there have been previous monographs dealing with certain broad aspects in its field. The author attempts to systematize existing knowledge and to some extent succeeds in outlining what is known in the field. The point of view is, however, by no means catholic but is essentially the psychobiologic point of view reached by the school of Adolf Meyer. Dynamic psychology is depreciated throughout. The neurologic principles included for completeness are not well outlined and are inadequately linked with the psychologic correlates. The practical basis is in name only since the actual procedures of treatment are barely indicated. On the whole the author has done a good piece of work in bringing together what data he has selected for the physician's consumption. It offers the pediatrician an interesting introduction to psychiatry.

Individual Health A Technique for the Study of Individual Constitution and Its Application to Health By E. Obermer Volume I Biochemical Technique By E. Obermer and R. Milton Cloth Price 15s. Pp 244 with 61 illustrations London Chapman & Hall Ltd 1935

This is the first of two volumes that will present a technic to be used by the physician of the future, whose principal concern will be the prevention of disease instead of its diagnosis and treatment, as is the case at the present time. In order to prevent disease, the maximum functional efficiency must be attained. To this end it will be necessary to make an exhaustive study of each individual to determine the part played by every factor—physical, psychologic or environmental—that may hinder or promote his efficiency, affect his resistance to infection or add to his longevity without senile loss of elasticity.

The authors propose a technic of "complete adaptation survey," which includes

- 1 Hereditary constitutional factors by
 - (a) detailed family history
 - (b) anthropometric measurements
- 2 External environmental factors by
 - (a) detailed past history
 - (b) physical examination
 - (c) bone radiology
 - (d) dental examination
- 3 Reaction of internal environment to present external environmental factor
 - (a) direct—by physical or mechanical means
 - (b) indirect—by biochemical means

This book deals with the second part of section three—the biochemical part of the technic. The entire remainder is to be presented in volume II.

The adaptational survey sets out to measure the functional efficiency of the individual the success with which he adapts himself to his particular environment. The authors propose a graph form to permit the linear expression in terms of physiologic equilibrium of the individual as he progresses through life. This necessitates repeating the third part of the survey at intervals of from one to five years up to death. The authors do not intend to deal with the interpretation or application of the observations in either of the two proposed volumes. This is to be reserved for a later consideration of these methods as applied to practical problems of individual health.

The elaborate investigation described requires a well organized laboratory unit for mass examinations. A personnel of eight can do four investigations in one day. The authors describe in great detail the organization and equipment necessary for the numerous examinations. The purpose of the biochemical section is to arrive at a quantitative picture of the

subject's dietetic and excretory habits. The ingesta of twenty-four hours are weighed and samples of each foodstuff analyzed. The blood, twenty-four hour urine specimens and twenty-four hour feces are then analyzed quantitatively and qualitatively. Eighty-seven different tests with more than a hundred examinations are necessary for each complete twenty-four hour survey of the subject's ingesta, excreta and blood examinations. About 175 determinations are necessary in addition to curves for the "metabolic equilibrium" report forms.

Part two of the book is of especial value to those interested in analytic chemistry. It presents in excellent form details of analytic technic. One method of analysis is selected for each constituent and many of the methods are photomicrometric or densitometric methods. These are especially valuable when one deals with large numbers of specimens. An excellent bibliography is included.

Personal and Community Health By Clair Elsmere Turner M.A. Dr P.H. Professor of Biology and Public Health in the Massachusetts Institute of Technology Fourth edition Cloth Price \$3 Pp 680 with 135 illustrations St. Louis C.V. Mosby Company 1935

A book for lay students by a layman, when it deals with basic sciences and their application for individual and collective health measures, concerns the medical profession. Professor Turner's contributions to the teaching of health from the nursery school level to that of the university student are well known and widely respected. The first 326 pages present the elements of anatomy and physiology and some of their applications to personal habits, particularly those of the young healthy adult of both sexes, together with a brief consideration of heredity, mental health, narcotics and stimulants. The next 200 pages give space to the larger problems of communal responsibilities, and organization for health protection. Environment, immunity, health administration, the hygiene of maternity, childhood, and industrial workers are simply presented in summary statements of long accepted facts. In a hundred pages of appendix are offered a reprint of the recent report of Control of Communicable Diseases, published in the August 9 *Public Health Reports*, and a review of disinfection and disinfectants. Except for the appendix report on communicable diseases, which is a document addressed to health officers and medical practitioners and is hardly understandable or usable in this concentrated form by college students, the book contains nothing novel or controversial. It is a straightforward, systematic exposition of matters of rather elementary character, the proper substance of teaching in a cultural arts course. It is a volume not likely to add materially to the useful knowledge of the graduate in medicine. The glossary and index are appropriate for the use of the type of expected readers addressed, but some of the definitions lack adequacy. "Pellagra, an endemic disease of the skin and spinal cord" "Labia, lips" "Virus, a living virulent cause of disease" "Yaws, a form of oriental sore in which the lesions consist of crust capped nodules."

Die rheumatische Infektion im Kindesalter mit besonderer Berücksichtigung der Grenzgebiete Von Dr. E. Glanzmann Professor der Kinderheilkunde an der Universität Bern Boards Price 5.40 marks Pp 83 with 36 illustrations Leipzig Georg Thieme 1935

The purpose of this monograph is twofold. It describes the clinical picture of rheumatic fever as seen in childhood and it describes those chronic diseases of the joints from which the articular manifestations of rheumatic fever must be differentiated. The author makes no attempt to describe acute inflammations of the joints and he excludes from consideration tuberculous and syphilitic involvement. In the section describing rheumatic infection, emphasis is properly laid on the fact that rheumatic fever is in reality a chronic and a systemic disease and that the articular manifestations constitute only one of a number of clinical varieties of rheumatic fever. The various clinical forms seen in childhood are described in turn. The present situation in regard to the etiology of rheumatic fever is discussed. The author points out the confused state of this phase of rheumatic fever and he emphasizes that the hemolytic streptococcus theory is far from demonstrated. The author discusses the medicinal treatment of rheumatic fever briefly and the use of phenylethylhydantoin in the treatment of chorea at some length. He cautions against the routine use of tonsillectomy. The presentation might have been improved

if the author had considered the differential diagnosis of the various forms of rheumatic fever in more detail and had discussed the long term management of this infection. In dealing with the other chronic involvements of joints, the author places particular emphasis on chronic systemic progressive polyarthritis and on Still's disease, which he considers separate entities. Still's disease is distinguished from the other form of chronic polyarthritis by the presence of intermittent fever, diarrhea, extreme cachexia, anemia, enlargement of the lymph nodes, splenomegaly, and cardiac involvement. The other types of joint involvement in childhood are briefly discussed. This monograph is to be recommended not only to pediatricians but also to physicians dealing with adults, because of the clear presentation of the picture of rheumatic fever and because of the fairly comprehensive review of the forms of joint involvement that may be encountered in young adults as well as in children.

The Physiology of Physical Education for Physical Educators and Their Pupils. By Percy M. Dawson, M.D. Cloth. Price \$8. Pp. 938. With 135 illustrations. Baltimore: Williams & Wilkins Company, 1935.

Here is an unusual textbook both in manner of presentation and in subject matter. The usual conventional limitations that beset the writer of most textbooks have not interfered with the irrepressible individuality of this author. The reader can not help but be impressed by the unusual yet scholarly manner in which the author presents his subject. He is a pioneer in textbook writing on subjects of biologic interest. There will be those readers who will immediately be out of sympathy with him for his lack of convention, but any one who will give this book a fair trial will be well rewarded for the effort. At first he will approach it cautiously, wondering what justification there is for the simplified spelling (even at times unorthodox). Later, after he has made an attempt to translate it, he will wonder again. He may finally have to accept it and admire both the author and the publisher for their courage. Perhaps he has undertaken too many ideals in textbook reform at one time. The material and mode of presentation are excellently chosen. Few books on this subject are as comprehensive and well correlated. The discussions on the physiology of muscle, nervous arcs, nutrition, growth and metabolism are particularly well done and contain almost all the recent data in the respective subjects. The chapters on sleep, fatigue, proposed aids to recuperation, exercise and human power and efficiency are only a few of the excellent evaluations of applied physiology. Any one interested in physical education will benefit greatly from this book. Physicians will also find this an excellent source of information not ordinarily available in the average textbook on the subject.

Über Erkrankungen des arteriellen Systems. Von F. Curtius R. Engel, H. Marx und R. Siebeck. Heft 1. Schriftenreihe zur Deutschen medizinischen Wochenschrift. Herausgegeben von L. v. Krehl, R. Siebeck und V. v. Weizsäcker. Boards. Price 3.60 marks. Pp. 102. With illustrations. Leipzig: Georg Thieme, 1935.

This monograph contains a series of five articles dealing with hypertension presented before the Medical Society of Berlin. Siebeck presents a somewhat theoretical discussion of the mechanisms of hypertension. Curtius emphasizes the need of considering in each individual the detailed family and personal history. Engel gives an excellent statistical summary of the relationship of the height of blood pressure to the prognosis of the patient with hypertension. This is based on 1,922 patients from the Heidelberg clinic and includes 884 who died. His careful analysis of statistical methods, with due regard to limitations, has led him to the conclusion that elevation of blood pressure foreshortens life, the prognosis being worse when the blood pressure is fixed at a constant high level. He recognizes that hypertension is not to be considered a systemic disease but rather as a symptom of a disturbance in function which has a definite prognostic significance. Even in patients with "chronic nephritis" the prognosis, he finds, depends on the elevation of blood pressure. Marx presents some experiments on the production of hypertension. He found that the injection of small quantities of streptococcus toxin into the ventricles of the brain of the dog produces hematuria, elevation of the blood pressure and an antidiuretic action. A similar effect is produced in the dog by the injection of spinal fluid from patients suffering with acute nephritis, but not by the cerebrospinal

fluid of normal individuals. Marx concludes from these experiments that one of the causes of hypertension is a disturbance in the function of the pituitary gland, but an examination of the evidence for this deduction will leave the reader far from convinced. Siebeck concludes the series of articles with a summary of some practical considerations of hypertension. He discusses the proper manner of taking blood pressure, the normal limits of blood pressure, the importance of the family history and the significance of cerebral symptoms. In discussing the therapy of hypertension he emphasizes the futility of lowering blood pressure, once hypertension is long established, because of the dangers of producing malnourishment in vital organs. The lowering of blood pressure he properly points out should be limited to the relief of disturbing symptoms. He emphasizes the need of rest, diet and certain general restrictions in the treatment of hypertension. He rightfully points out the lack of proved value of the various depressor substances obtained from organ extracts that have been advocated in the past. Physical therapy, graded exercise and psychotherapy, he believes, play a more important part in controlling the blood pressure level than medicinal treatment. This booklet should prove stimulating to the medical reader.

A Textbook of Anatomy and Physiology. By Jesse Felsing Williams, M.D. Professor of Physical Education, Teachers College, Columbia University, New York City. Fifth edition. Cloth. Price \$2.75. Pp. 646. With 416 illustrations. Philadelphia & London: W. B. Saunders Company, 1935.

This book, according to the author, "is arranged to serve the needs of the student of anatomy and physiology outside the medical school," including students of nursing, physical education or one of the allied fields whose problems are fundamentally alike. The arrangement is excellent. Each chapter is headed with a convenient outline and closes with practical lesson helps. The book is written from the broad point of view of the author, which reflected through all his writings, has placed him in the forefront among health educators as well as in the field of physical education. Of the authenticity of the material presented there can be no question, the form of its presentation makes this a workable textbook which should be a great aid to the student of anatomy and physiology, which the author admits are difficult subjects. For the students for whom he writes, the author says, "no shallow descriptive anatomy and physiology will suffice." Instead, he insists that they shall be "acquiring fundamental concepts of human structure and function." The occasional evidences of gullibility exhibited even by well educated persons, including teachers, in the presence of plausible medical fakes, lends point to the insistence that workers with human material, such as teachers and nurses, shall be soundly grounded in the "fundamental concepts of human structure and function." For such a grounding Dr. Williams presents the materials in a form as readily assimilable as the inherent difficulties of the subject permit. A good glossary and index and numerous illustrations of excellent quality should be helpful to the student. The book can be recommended without reservation.

Röntgenbefund und pathologisch-anatomischer Befund bei Lungenkrankheiten. Versuch einer kritischen Vergleichung. Von Dr. med. Max Versé, o. ö. Professor der allgemeinen Pathologie und pathologischen Anatomie, Marburg. Teil 1. Text. Teil 2. Atlas. Cloth. Price 18 marks. Pp. 93, 144 illustrations. Berlin: Otto Elsner Verlagsgesellschaft m. b. H., 1935.

This book consists of two volumes. Volume I consists of ninety-three pages giving brief clinical histories of fifty-four cases of lung disease, representing the various types, chosen from a large collection of pathologic material. In addition to the clinical history there is a description of the pathologic changes shown by fluoroscopic and roentgenographic studies in comparison with the gross and, at times, the microscopic studies of the pathologic changes.

Volume II is an atlas with 144 full page illustrations showing the conditions described in volume I. Primarily, this work represents the pathologist's work, and most of the illustrations represent the lungs as shown in roentgenograms, with the lungs after the removal from the body deflated, partially inflated, and completely inflated, with associated light photographs of the pathologic specimen in cross section. In a few cases there are shown roentgenograms made during life, but most of these

were made a considerable time before death. The author has shown especially the difficulties of demonstrating small atelectatic areas and has especially emphasized the fact that the roentgenographic appearance often represents atelectasis added to the primary pathologic condition.

The work illustrates how important it is for pathologists to combine roentgenographic and fluoroscopic studies with the macroscopic investigations. It also conveys to the clinical radiologist and to the general clinician a rather definite idea of the pathologic processes that take place in the various diseases. From the standpoint of the clinical radiologist and the general clinician, it is to be regretted that there could not have been shown more of the roentgenograms taken during life, for it is such roentgenograms on which the clinician must depend for the proper treatment of the patient.

This work is of special interest and should be in the library of every pathologist and physician who is giving special attention to diseases of the lungs, also it should be a part of the roentgenologist's library.

A Course of Study in Dentistry. Report of the Curriculum Survey Committee. American Association of Dental Schools. Paper. Price \$1. Pp 413. Chicago. The Committee. 1935.

The survey represents an effort on the part of dental educators to apply to their problems the same scientific methods that are now employed in other fields of education. It is not an evaluation of present practices, rather it attempts to determine, in the light of human needs, what constitutes an adequate undergraduate dental curriculum. The authors recognize that no course of study, however well it may be designed or however solid its foundations, can ever be final; that provision must be made for constant readjustment in the light of newer knowledge and clearer understanding of the public need. In its final recommendations the committee unhesitatingly declares itself in favor of the four year dental curriculum based on admission requirements of two years in college. This declaration will doubtless settle the long standing controversy regarding the length of the dental course. The committee also endorses the policy of maintaining dental education as an independent and autonomous field of professional education. Doubtless this handbook will serve a useful purpose, especially in assisting the weaker schools to improve their curriculums, but the adoption of a detailed syllabus of instruction seems to be a procedure better adapted to secondary education than to instruction at the university level.

The Theory and Practice of Anæsthesia. By M. D. Nosworthy. M.A. M.D. B.Ch. Anæsthetist to Westminster Hospital, London. With a foreword by I. W. Magill. M.B. B.Ch. Senior Anæsthetist to Westminster Hospital, London. Cloth. Price 12/6. Pp 223 with 35 illustrations. London. Hutchinson (Scientific). 1935.

The author has written a short book in which he has not attempted to cover the whole subject of anesthesia but in which he has gone into detail concerning methods of anesthesia that can be applied in every type of case. He says that many of the points in the book may appear trivial to experts but that they have helped many resident anesthetists. It can be said that the book will be of such satisfaction to experts that their work in teaching will be made much easier and many of their ideas will be reflected independently in the book. One chapter deals with the mode of action of inhalation anesthesia and it is well done. Another chapter is on postanesthetic acidosis, which reviews the existing opinions well. In a chapter on the influence of certain factors during anesthesia the author stresses the use of carbon dioxide and oxygen and points out the many valuable uses. A chapter on shock covers the practical points well. The stages and signs of general anesthesia are discussed.

The chapter on ether and the difficulties in general anesthesia, which includes a discussion of respiratory obstruction and respiratory abnormalities, is without doubt the best of its kind in print on the subject. The use of ethyl ether is thoroughly covered, and reference is made to vinylene. The chapter on chloroform is excellent and is valuable to anesthetists in the United States because they seldom use it and yet should know about it. The next chapter, on ethyl chloride, is short but good. The following chapter, on nitrous oxide, is almost as short but equally good, and the one on nitrous oxide and oxygen is excellent and covers that subject especially well.

The author speaks briefly of other anesthetic gases. There is a chapter on endotracheal anesthesia, which is good. The chapter on preliminary medication is particularly good and includes a discussion of the rectal and intravenous use of certain drugs. The chapter on regional anesthesia deals with spinal anesthesia, with the use of only nupercaine and stovaine, and reflects the author's experience with it and the results reported by others. The choice of an anesthetic is dealt with briefly, as are the after-effects of anesthesia. The English speaking anesthetist would do well to read this book.

Review of Legal Education in the United States and Canada for the Year 1934. By Alfred Z. Reed. Staff Member in Charge of the Study of Legal Education. Paper. Gratis. Pp 75. New York. Carnegie Foundation for the Advancement of Teaching. 1935.

As customary, Mr. Reed devotes a large portion of his report to the discussion of a single theme, in this case, "The Salaried Professor in the Learned Professions." He finds the origins of the teaching professions in the apprenticeship customs and the craft-guild organizations of the Middle Ages and recounts the influences, economic and social, which have modified the status of the teacher from that day to this. The varying structure of European and American universities is portrayed and special emphasis laid on the significance of state and municipal universities. A chapter devoted to the "Institutional Development of Medicine, Law, Engineering, and Architecture" presents interesting comparisons of the educational policies of these professions. With respect to the activities of the American Medical Association there is on page 24 an unfortunate misstatement. The Council on Medical Education and Hospitals by no means "recognizes the Association of American Medical Colleges as the standardizing agency for all educational matters."

Tumeurs de l'encéphale. Contributions à l'étude anatomo-clinique des tumeurs intracrâniennes et du repérage ventriculaire. Par D. Paulian. Préface du Docteur Clovis Vincent. Paper. Price 30 francs. Pp 215 with 189 illustrations. Paris. Masson & Cie. 1935.

This monograph consists of three parts: the first dealing with the pathologic anatomy of intracranial tumors, the second with ventriculography and the third with a series of forty-six cases of neoplastic disease affecting the brain. The French of the author is none too good, and typographic errors are innumerable. He follows the classification of Hortega in the first seven pages and then suddenly shifts to that of Bailey and Cushing, making it difficult to correlate the two discussions. There are numerous incorrect statements in this part, such as that the oligodendrogliomas are encapsulated and that microscopically the medulloblastomas are easily confused with the spongioblastomas. He details at great length the outworn conception of a neurospongium. In the second part great emphasis is placed on Laruelle's method of ventricular visualization. Any one with any experience with this method knows how readily one may misinterpret the roentgenograms obtained in this way. The third part details a series of forty-six neoplasms of all kinds and locations, many metastatic. Many American clinics could fill libraries with such case reports. The American student will learn nothing from this disjointed discussion.

Meharry Medical College. A History. By Charles Victor Roman. Professor of Philosophy and Social Ethics. Tennessee A. and I. State College. Cloth. Pp 224 with 43 illustrations. Nashville. Sunday School Publishing Board of the National Baptist Convention, Inc. 1934.

The author states in the introduction that, like the writer of the Epistle to the Hebrews, he is appealing to his own. His audience he describes as alumni of Meharry Medical College, alumni of Howard and Shaw, those of Negro blood wherever they were graduated and wherever they reside, all who love or practice the principles of the healing art of whatever language, race or country, and finally the friends of human progress, whatever their specific interests or occupations. The story of Meharry Medical College is told in brief sketches of the men who have been prominently connected with it, the founders, successive presidents, and members of the faculty. Personal impressions predominate and there is little attempt to appraise the educational significance of the institution. It will serve as a eulogy of the courage, perseverance and utterly unselfish devotion of George Whipple Hubbard, dean and president from 1876 until his death in 1924.

Medicolegal

Workmen's Compensation Acts Compensability of "Chemical Conjunctivitis"—The claimant, in the course of her employment, handled dresses made of goods containing certain dyes. She had an attack of conjunctivitis in 1926 and another in 1927, which her physician diagnosed as "chemical conjunctivitis" and attributed to the dyes in the dresses she handled. She applied to the industrial commission of Ohio for compensation under the workmen's compensation act. The commission denied her claim but on appeal the court of common pleas allowed it and the order of that court was affirmed by the court of appeals. The industrial commission then appealed to the Supreme Court of Ohio. The claimant alleged that particles of the dyes in the goods she handled became detached, some of them sticking to her hands and others floating in the air, and that these detached particles thus came in contact with the mucous membrane of her eyes and caused the conjunctivitis that was the basis of her claim.

"Chemical conjunctivitis," said the Supreme Court, is not an occupational disease within the category of occupational diseases defined by the legislature in the workmen's compensation act of Ohio. If it is compensable at all, the claimant must prove that it is the proximate result of traumatic injury received in the course of her employment. There was no testimony to show that particles of dye did adhere to the claimant's hands and by rubbing were transferred to her eyes or that such particles floated in the air. She herself testified that she never rubbed her eyes. Her physician's diagnosis of chemical conjunctivitis was based on the history given by the claimant and on the fact that the condition did not yield readily to treatment. No microscopic examination was made to prove or disprove the presence of particles of dye on the claimant's hands or in the air. Her physician's testimony was to the effect that the actual cause of the claimant's condition was unknown to him but that particles of dye could have caused it.

The condition of the claimant's eyes may have been due to some external irritant sufficient to constitute "medical trauma," but, asked the court, was it "legal trauma," or the kind of trauma that the legislature had in mind when it enacted the workmen's compensation act? If the court should hold that, when microscopic particles of dye come in contact with the uninjured mucous membrane of the eye they cause trauma within the meaning of the law, it would be obliged to hold that trauma resulted whenever any microbe entered the body from the outside and lodged on an uninjured mucous membrane. Such a holding would upset all legislation relative to occupational diseases. Even if it should be admitted, continued the court, that the dress goods handled by the claimant gave off particles of dye, which were communicated to her eyes in the course of her employment, the claimant still would not be within the purview of the workmen's compensation act, for the claimant herself testified that nothing unusual had happened to her. Therefore there was no accidental injury within the meaning of the law.

The judgment of the court of appeals was reversed and the order of the industrial commission of Ohio denying compensation was affirmed—*Industrial Commission of Ohio v. Armacost (Ohio)*, 194 N. E. 23.

Chiropractic Jurisdiction of Kentucky Chiropractic Board Over License Issued by State Board of Health.—The state board of health of Kentucky in 1924 licensed J. E. Triplett to practice chiropractic and physical therapy, pursuant to a Kentucky statute authorizing the board to issue licenses to practitioners of any drugless or limited school of treating human ailments. In 1928 the legislature passed an act creating a board of chiropractic examiners and conferred on that board the right to issue and revoke licenses to practice chiropractic. Subsequently, proceedings were instituted before the state board of health to revoke Triplett's license. He petitioned the circuit court for an injunction to restrain that board from action against him, contending that the chiropractic practice act of 1928 divested the state board of health of jurisdiction

to revoke chiropractic licenses. The court sustained a demurrer by the state board of health. From a judgment dismissing his petition for an injunction, Triplett appealed to the Court of Appeals of Kentucky.

In the opinion of the Court of Appeals, it was clearly the purpose of the legislature, in enacting the chiropractic act of 1928 creating the state board of chiropractic examiners and defining its powers and duties, to give that board jurisdiction over all licensed chiropractors, including those to whom licenses had been issued by the state board of health prior to passage of the act. It necessarily followed that after the effective date of the act the state board of health was without authority to revoke a license to practice chiropractic even though the license had been granted by it.

Triplett's license, however, authorized him not only to practice chiropractic but also to practice physical therapy. The court was unable to determine from the record whether or not physical therapy was a drugless or limited school of healing. Assuming that it was, the court concluded that the authority of the state board of health to revoke a license to practice physical therapy for causes specified by statute was not affected by the act of 1928 creating the board of chiropractic examiners.

The judgment of the circuit court was reversed. The case was returned to the trial court for proceedings consistent with the decision of the Court of Appeals that the state board of health had no authority to revoke Triplett's license so far as it related to the practice of chiropractic but that it had authority to revoke it so far as it related to the practice of physical therapy—*Triplett v. State Board of Health (Ky)*, 79 S. W. (2d) 226.

Privileged Communications Privilege Not Waived by Cross-Examination of Lay Witness Present at Examination of Patient.—On June 9, 1930, the defendant insurance company delivered a policy on the life of the deceased. On April 23, 1931, she died. The certificate of death issued by the attending physician gave tuberculous laryngitis as the immediate cause of death. The insurance company refused to pay the benefits named in the policy, claiming that when the policy was issued the deceased had been treated for pulmonary tuberculosis and that her statements to the contrary in her application were false and fraudulent. The plaintiff, individually and as administratrix of the deceased's estate, sued the insurance company. From a judgment in her favor the company appealed to the Supreme Court of Nebraska.

Sometime preceding her application for life insurance, the deceased was taken sick. Her roommate accompanied her to the office of a Dr. Betz and was present when he made his examination and gave advice. The roommate made a deposition in the present case in the course of which she was cross-examined by counsel for the plaintiff and which was admitted in evidence. Later when the defendant offered in evidence the deposition of a Dr. Fiske, who had treated the deceased subsequent to her visit to Dr. Betz, the plaintiff objected, on the ground that Dr. Fiske's deposition contained a privileged communication between physician and patient and was therefore inadmissible, since the deceased had not waived her privilege. The defendant insurance company contended, however, that the plaintiff had waived the privilege of her intestate by reading to the jury the cross examination of the roommate of the deceased, who had been present when she was examined and advised by Dr. Betz. The reading of that cross examination, the defendant contended, waived the privilege as to any and all doctors who had treated the deceased.

In the cross-examination of the deceased's roommate, said the Supreme Court, the counsel for the plaintiff did not seek to introduce evidence on his own case. His cross examination may be considered as a limitation or modification of the answers made by the witness on direct examination. Nothing indicates that he sought independent evidence, and such a cross-examination cannot be considered as the evidence of the party who calls the witness, unless that party goes too far afield in his examination. The argument that the deceased, by taking a third person with her into the examining room of her physician, waived her privilege of professional secrecy did not appeal to

the court. It did not seem to the court to constitute a waiver of confidential relations. The cross-examination of such a third person when she has been called by the other side to answer questions that are unobjectionable is not a waiver of privilege. The privilege of secrecy should be jealously guarded to protect the rights of one whose lips are closed in death.

The weight of the evidence did not, in the judgment of the Supreme Court, show that the insured had made any untrue answers in her application for insurance. The judgment of the court below was affirmed.—*Leeds v Prudential Ins Co of America (Neb)*, 258 N W 672

Workmen's Compensation Acts Compensability of Injury Impairing Physical Function but not Earning Capacity—An employee developed a perforation of his nasal septum because of the inhalation of chrome in the course of his employment. The perforation was permanent but it in no way disabled the employee in the discharge of his duties or diminished his earning capacity. He claimed and was awarded compensation, however, under the workmen's compensation act. The court of common pleas affirmed the award and thereupon the employer appealed to the supreme court of New Jersey. The employer contended that his employee's injury was not compensable, because it was neither incapacitating nor disabling. Medical witnesses testified that branches of the olfactory nerve distributed through the septum had been destroyed or permanently impaired, resulting in a diminution of the employee's sense of smell. This, said the supreme court, is a compensable injury even though the employee's capacity to perform his work is not impaired or his earning capacity diminished. The test of compensability under the workmen's compensation act of New Jersey, said the supreme court, is not impairment of earning capacity but rather the "loss of physical function which detracts from the former efficiency of the body or its members in the ordinary pursuits of life." The supreme court refused to review the decision of the court below.—*Sutkowski v Mutual Chemical Co of America (N J)*, 178 A 71

Workmen's Compensation Acts Insurer Liable for Payment for Medical Services Rendered Injured Employee—The hair of an employee, in the course of her employment, caught in a revolving shaft and "her scalp and back of neck were torn off." The hospital to which she was taken called the physician-claimant, a member of its staff, who was not "on service" at the time but was subject to call for emergency cases, to render emergency treatment. On the day of the accident, but after the admission of the employee to the hospital, her father selected as her physician the physician who had already rendered emergency treatment. This physician treated her for several months in the hospital, performing several skin graftings and looking after manipulations of the neck muscles at intervals. No express contract was made between the employer's insurer and the physician-claimant as to compensation, but the insurer knew that the physician-claimant was treating the case. The insurer paid the compensation due the injured employee and paid the hospital bill but refused to pay the physician for his services. The physician then instituted proceedings under the workmen's compensation act, before the industrial accident board against the employer and the employer's insurer. From a decree of the superior court, after certification from the industrial accident board, in favor of the physician the insurer appealed to the Supreme Judicial Court of Massachusetts.

The workmen's compensation act of Massachusetts requires the insurer to pay the reasonable charges for services rendered by a physician when the employee selects a physician other than the one provided by the insurer and in case of emergency or other justifiable cause. The industrial board held that the employee, through her father, had selected the physician-claimant as her physician and that the insurer should pay a reasonable fee for his services, because there was justifiable cause within the meaning of the act for his continuing treatment of the injured employee as his private patient. The insurer contended that there was no evidence to support the board's finding.

While there is no evidence said the Supreme Judicial Court that the employee herself expressly selected the physician

claimant as her physician, her acceptance of his services for many continuous months clearly warranted the inference that she ratified and adopted his selection by her father. The insurer further contended that a physician on the staff of a general hospital is not entitled to compensation from an insurer for his services to a patient in that hospital, in the absence of any contract with the insurer, especially when the treatment was not begun as that of a private patient and was continued in the same hospital by the same staff physician and when the hospital had been paid for its services by the insurer. Apparently the insurer's contention was that the case originally was a staff case of the hospital and not a "private" or personal case, that it continued as a staff case, and that therefore a staff physician of the hospital, the hospital itself having been paid, was not entitled to compensation for his services. This argument did not appeal to the court. Although, said the court, the treatment did not begin as that of a "private patient," it was considered as such following the employment of the physician by the employee's father. In this case there was both an emergency and a selection of a physician after the employee had recovered consciousness. The exact moment of such selection was immaterial.

The court affirmed the decree awarding payment to the physician for his services.—*Zombrie's Case (Mass)*, 195 N E 312

Evidence Admissibility of Complaints Made to Physician Examining Only to Qualify as Witness, Medical Examination of Plaintiff in Presence of Jury—In the course of the trial of this personal injury case, the plaintiffs called as a witness a physician who had examined one of them for the sole purpose of enabling him to testify as to her physical condition. In the course of this physician's testimony the trial court permitted him to relate statements made to him by the plaintiff whom he had examined. These statements embraced (1) complaints of present pain and suffering, (2) complaints showing present subjective symptoms and (3) the history of her injuries, including some history of past suffering. Counsel for the defendants repeatedly objected to the admission of such statements on the ground that they were hearsay. The witness however, declared that a narration of what the plaintiff told him was important in the light of his physical findings and opinion. Judgment was rendered for the plaintiffs and the defendants appealed. On appeal, the district court of appeal, second district, division 2, California, found no error in the admission of this testimony holding that—

On the trial of cases for damages for personal injuries complaints by the injured party of present pain and suffering are admissible on proper foundation as evidence through the medium of either medical or lay witnesses. *Bloomberg v Laventhal* 179 Cal 616 178 P 496. *Kimball v Northern Electric Co* 159 Cal 225 231 113 P 156. Declarations and statements made to an examining expert by an injured party of previous condition and past suffering when declared by the expert to be necessary to enable him to form an opinion as to the nature and extent of the disease or injury and when such statements constitute in part the basis upon which the opinion of the expert is based are admissible not for the purpose of establishing the truth of the statements but to serve as a basis for the medical opinion the expert is about to give. *People v Shattuck* 109 Cal 673 42 P 315. *Davis v Renton* 113 Cal App 561 298 P 834. *Rohner v Cross* 121 Cal App 667 9 P (2d) 509.

In the course of the trial a medical witness was permitted to manipulate the plaintiff's neck with his fingers and to "pinch" her cervical vertebra, in the presence of the jury, causing the plaintiff to cringe and to twist her body, with accompanying registration of pain by her facial expression and contortion. This was in the nature of a medical examination of the injured parts and amounted to what might be termed a demonstration. The district court of appeal refused to consider such a demonstration as error. Reception of such evidence, it said, lay primarily and largely in the discretion of the trial court, and it would be only in case of a plain abuse of such discretion that an appellate court would interfere. Such a demonstration may open the door to deception or encourage malingering, or unduly arouse the sympathy of the jury, and it may therefore require a greater degree of care on the part of the trial judge in exercising the discretion vested in him. The existence of such contingencies however, are not recognized as sufficient to forbid the reception of such evidence in cases such as this.

The trial court heard and saw the whole demonstration and was in a situation peculiarly favorable to determine whether it was prejudicial to the defendants. There was no basis, therefore, for substituting the discretion of the appellate court for that of the trial court.

The judgment in favor of the plaintiffs was affirmed—*Willingby v Zylstra (Calif.)*, 42 P (2d) 685

Workmen's Compensation Acts Heat Stroke an Accidental Injury, Autopsy Not Necessary to Prove Cause of Death—The appellee filed a claim for compensation under the workmen's compensation act of Montana, asserting that her husband died as the result of heat stroke. His employer, the appellant, introduced evidence to show that he died of myocarditis. The appellee, the widow, had thought an autopsy unnecessary, and the coroner rejected the suggestion made by a physician employed by the appellant that he order one. The facts and circumstances of this case, said the Supreme Court of Montana, on appeal, bear out the claim that the deceased died from exposure to heat. With the contention of the appellant that it was necessary for the widow to prove the cause of death by the best possible evidence, which must be based on autopsy, the court could not agree. It would be entirely violative of the principles of the workmen's compensation act to hold that the widow, because she had not had an autopsy made on the body of her husband, forfeited her rights under the act. The obligation to take every necessary step to preserve evidence to establish the cause of death rested on the employer, its superintendent, and its medical adviser, at least as heavily as it did on the widow of the dead workman. The judgment of the district court awarding compensation to the appellee was affirmed—*Birdwell v Three Forks Portland Cement Co (Mont.)*, 40 P (2d) 43

Medical Practice Acts License Obtained by Fraud Revocable—The board of medical examiners of California, in 1922, issued to Eugene J. Rinaldo a license to practice medicine, on the basis of a license issued to him by the Missouri state board of health. Complaint was filed against Rinaldo before the California board of medical examiners, April 28, 1924, charging him with having procured his California license by fraud and misrepresentation, in that he falsely stated in his application that he had a medical diploma from the St. Louis College of Physicians and Surgeons, issued in 1908, and that prior to his matriculation at that college he had all the preliminary education required by the medical practice act of California, whereas he did not have such a diploma and never had a bona fide certificate of preliminary education. After litigation extending over eight years, Rinaldo's license was finally revoked, Oct. 18, 1932. The superior court, in certiorari proceedings, annulled the order of revocation, and the board appealed to the district court of appeal, second district, division 2, California, thus bringing the case before that court for the fifth time.

The fact that Rinaldo did not appear at the hearing at which his license was revoked, said the district court of appeal, was immaterial. He was cited to appear and had reasonable notice and opportunity to be heard. That was all that was necessary to give the board jurisdiction. The evidence before the board showed that in 1918, through a solicitor for the St. Louis College of Physicians and Surgeons, Rinaldo purchased from the assistant superintendent of public instruction of Missouri a certificate of high school credits, and from a physician in Los Angeles a certificate of four years' medical education in the Pacific Medical College. That in October 1918 he enrolled in the College of Physicians and Surgeons of St. Louis, and that he studied there until April 1919 and was graduated by that school in June 1919. The trial court, in certiorari proceedings, held that the evidence adduced was insufficient to warrant the revocation of the license, but on appeal the district court of appeal took a different view.

The writ of certiorari said the court, can be used only to ascertain whether the board exceeded its jurisdiction. The action of the board is final and conclusive on every question other than that of its own jurisdiction. When the state board of medical examiners is vested with authority to determine the guilt or innocence of a person charged with an offense under

the medical practice act, as the board was in this case, its determination of the question of guilt or innocence, however erroneous it may be, is not void for want of authority in the board to render it. Only where it appears that there is a total lack of competent evidence on which the board's adjudication could be based can a review of the evidence by the court be had to determine whether facts adequate to give the board jurisdiction were or were not proved. The board in this case, on competent evidence, made its determination, and neither the superior court nor the district court of appeal may substitute its determination for the determination of the board.

While the right of a person to practice a profession for which he has prepared himself is property of the very highest character and entitled to protection, the legislature may authorize the board of medical examiners to revoke the licenses of persons whose principles, practices and characters make them unfit to remain in the medical profession. Any fraud or misrepresentation in the application on which a license to practice medicine is based, resulting in giving the appearance of qualification to a person who does not in fact possess it, is sufficient under the law to warrant revocation of that license. The judgment of the superior court, annulling the board's revocation order, was reversed.—*Rinaldo v Board of Medical Examiners of State of California (Calif.)* 42 P (2d) 724

Hospitals Liability for Care of "Non Compos Mentis" Patients—According to the court of appeals of Georgia, division 2, "A private hospital [for the treatment of patients suffering from nervous and mental diseases] in which a patient is placed for treatment owes the duty of safeguarding and protecting the patient from any known or reasonably apprehended danger from himself which may be due to his mental incapacity, and to use ordinary and reasonable care to prevent such danger, and where the patient, while in the care of the hospital, is, with the knowledge of the authorities in charge of the hospital having him in care and charge, temporarily insane and in a mental condition where he may possibly do injury and harm to himself or others, and the authorities negligently fail to so care for and keep the patient, and by reason thereof he has access to a knife or other sharp instrument, which he uses in killing himself by cutting his throat, the authorities of the hospital are guilty of negligence as respects their duty to keep and care for the patient which is the proximate cause of the homicide, and are liable in damages therefor to the person legally entitled to recover"—*Browner v Bussell (Ga.)*, 179 S E 228

Current Medical Literature

AMERICAN

The Association Library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Blood Lipids in Eclampsia—Boyd found that the concentration of lipids varied greatly in eclamptic patients, but no significant variation occurred in the value of any single lipid. The ratio of phospholipid to cholesterol in plasma was found, however, to be without exception higher in eclampsia than in other toxemias or in normal gestation. The mean minus the standard deviation for the ratio in eclampsia was higher than the mean plus the standard deviation in normal gravidas and other toxemias. Variations in the value of the ratio from one eclamptic patient to another were only one fourth to one third as great as the variation in single lipids indicating that the ratio was also less variable than the component lipids. When the patients recovered from eclampsia the ratio phospholipid/total cholesterol of plasma returned quickly to normal, owing chiefly to a fall in the value of phospholipid. Cessation of convulsions without termination of pregnancy left the ratio still high, indicating that a high ratio did not result from convulsions but was associated with and possibly accounted for the eclamptic state. Only a small proportion of cases diagnosed as preeclampsia were found to show an elevated plasma phos-

pholipid/total cholesterol ratio and, hence, were literally preeclamptic. The test is at present being used as a means of separating the preeclamptic group into true preeclampsia and nonconvulsive cases. The relation of water retention to convulsions becomes more apparent if attention is confined to the tissues of the brain. Increased water retention by the brain, due to an increased plasma phospholipid/total cholesterol ratio favoring increased phospholipid values in the brain will result in increased pressure within the bony skull. When this surpasses a certain maximum, the irritability of the nerves may reach a point at which convulsions ensue. The explanation, deduced from the present data, is offered as a working hypothesis not as a proved theory.

Blastomycosis of Female Reproductive Tract—Hamblen and his associates recount their study of a case of infection of the fallopian tube and uterus with *Blastomyces dermatitidis* in a patient with arrested pulmonary blastomycosis (American type, Gilchrist's disease). A preoperative diagnosis of uterine involvement was made from a section of endometrial curettings and confirmed by culturing the organism. Mycologic and anatomic studies of the removed tissues are recorded. This apparently constitutes the first report of extensive blastomycosis of the female reproductive tract. The tissue reaction in the affected organs was remarkably like that in tuberculosis but was to be differentiated from the latter by the presence of the double-contoured blastomycetes. The removal of the uterus was necessary to prevent further excessive blood loss, and the extirpation of the tubo-ovarian masses was indicated to eliminate the large blastomycotic focus. Surgery was justified in this case by the uncomplicated postoperative course.

Complications Following Cauterization of Cervix Uteri—Cannell and Douglass have observed a number of complications following cauterization, three of which are reported. The complications have followed cauterizations after the heavy duty or Paquelin cautery, or the postcautery in office practice. Very light surface cauterization with the finer types of cautery is definitely advisable but is less effective. The occurrence of widespread pelvic infections following cauterization is evidently much more frequent than is commonly supposed. The presence of a latent gonorrheal infection of the cervix should be carefully eliminated whenever possible. Patients with a history of infected abortion, especially of recent occurrence, should be dealt with most cautiously as subjects for cervical cauterization, especially with the heavy duty cautery. The authors also have had an instance of pelvic inflammatory disease, apparently immediately initiated by office cauterization for erosion of the cervix in a patient with adherent retroversion of the uterus and one-child sterility of a duration of seven years. This patient had had a number of negative smears and had no local stigmas of gonorrhea. The cautery should be employed with extreme care and circumspection and with the knowledge that severe cellulitis may result occasionally as a complication.

Tendon Transplantation in Ocular Muscle Paralysis—O'Connor emphasizes the need to have cases of ocular muscle paralysis under the observation, from their onset of an ophthalmologist who is able to handle them surgically, in order that operation may be done as soon as it becomes certain that the paralysis is permanent and before contractures have developed.

in the opponents. He disproves the contention of some authorities (Bielschowsky) that transplantations are not worth while because of a mistaken idea that binocular action is never secured. Binocular vision is secured, at least in positions near the primary, in all cases that have come to operation before contractures have occurred. He believes that the operation of choice is his new one by which the tendon halves farther from the palsied muscle are used. In case of an abducens palsy the nasal halves of the vertical recti are transplanted. The cinch loop, of course, must be used for secure anchorage in the transplants. General results in a series of operations by different methods are given.

Interrelation of Gynecologic and Gastro-Intestinal Symptoms—Moench points out that, considering the close proximity of the genital organs to all others in the abdominal cavity and the interrelation of the blood supply and the general and autonomic nervous innervation, it would be strange if disturbances in the genital system did not affect the gastro-intestinal system, and vice versa. That markedly relaxed abdominal walls and relaxation of the pelvic floor may cause gastro-intestinal symptoms goes without saying, and he has cured many such cases by perineal repair and a proper belt. In every female patient with gynecologic or gastro-intestinal symptoms or both, one must first determine whether an organic lesion is present, and, secondly, where it is situated. After an organic lesion has been found, one must carefully evaluate whether it can explain all the symptoms the patient complains of and whether the symptoms referred to one organic system can be explained by the organic change present in the other

It must not be forgotten that the gynecologic lesion may obscure or hide gastro-intestinal symptoms or contrarily cause only gastro-intestinal disturbances, or that the gastro-intestinal lesion may produce only gynecologic symptoms. If organic changes are found in both the gynecologic and gastro intestinal systems, it must be determined whether or not the two lesions are separate entities or whether they are interrelated and, if the latter, in what way. At times, however, no organic lesions are discovered or the lesions actually present cannot possibly explain the patient's gastro-intestinal or gynecologic complaints. It is here that a painstaking and tactful anamnesis is of inestimable value. But further than this, one must know of the patient's habits. Nostalgia or grief may cause gastro-intestinal upsets as well as gynecologic symptoms. Nausea and vomiting may appear only near the menstrual period, perhaps owing to pelvic congestion. In other cases the reaction is a psychic revolt against menstruation because of a desire for offspring. After coitus gastro-intestinal symptoms may come on. Roentgen treatment for uterine fibromyomas may cause diarrhea. Asthenic conditions and even gonadal insufficiency, coupled with other hormone defects, may cause symptoms simulating gastro-intestinal disease. It is evident that routine treatment is impossible. Sometimes a mild sedative will alleviate gynecologic and gastro-intestinal symptoms quicker than any complicated specialized treatment. Again, a sympathetic attitude and reassurance of the patient in regard to her gynecologic troubles will cure gastro-intestinal distress.

Bacteriophage Therapy—The experience of Lampert and his associates with bacteriophage in the treatment of certain types of infections, chiefly carbuncles, furunculosis and hand infections, is based on approximately 1,000 cases and has resulted in more than 90 per cent of successes. They consider their successful results to be due in large measure to the technic of application, which is based on direct contact of the bacteriophage with the infected tissues by means of generous daily applications. The prompt relief of pain and the brief duration of treatment by bacteriophage therapy, as compared with the duration of treatment by other measures, are noteworthy clinical facts. The method does no harm in cases in which it does not succeed.

Involvement of Spinal Meninges and of Bone in Undulant Fever—Marietta reports a case with involvement of the spinal meninges and of the lumbosacral joint, which is considered the result of infection by *Brucella melitensis*, bovine type, and has been observed over a period of two years. The patient finally returned to his usual occupation. The question in his case is the accuracy of the diagnosis, that is, whether, with no positive cultures obtained from any source, a definite diagnosis of brucella infection is justified on the basis of the history, clinical course, positive agglutinations and the apparent elimination by laboratory study of other possible factors. While it cannot be said that there is any specific agglutination titer that is diagnostic, a titer of 1:80 is generally so accepted, the titers are generally not so high as in the present case, except in the presence of an active infection, those due only to antibodies from the use of infected milk being in the low range,

at least below 1 100 Negative cultures of the blood, pus, urine, and the like may be explained as being due to the age or chronicity of the condition, positive cultures being obtained usually in the early stages Tuberculosis may be eliminated as a causative factor in the case by the negative history, the absence of tuberculous lesions elsewhere in the body, the numerous negative smears and cultures, the roentgenographic appearance of the bone lesion, which is entirely different from that seen in tuberculosis of the bone, that is, too little of a destructive and too much of a regenerative process, and more specifically by the numerous negative animal inoculations Typhoid is eliminated by the numerous negative cultures of the urine, blood, pus and stools, by the clinical course and, inferentially at least, because of the fact that the patient had previously had several courses of typhoid vaccine Actinomycosis was ruled out Syphilis was not a factor, as evidenced by the repeated negative serologic observations In favor of brucella as the etiologic factor are the undulant and irregular type of fever, mild secondary anemia, general low white blood count with low polymorphonuclears, marked sweating, loss of weight, orchitis, cough with abundant mucopurulent expectoration, long duration of the disease, positive agglutinations and elimination of other infectious agents The late development of bone involvement as a complication of brucella infection, mentioned by Roger, was exemplified by being demonstrated twelve months after the beginning of the patient's illness, abscess formation did not take place until three months after the first bone changes were noted The author states that his treatment probably left something to be desired as a formulated plan carried out to its completion Pyronin dye seemed to have a definitely beneficial effect when injected into the abscess tracts, and goat's serum and antiabortus vaccine were also markedly effective in the relief of subjective and objective symptoms The patient himself noted and remarked on the relief that he experienced from these remedies Intravenous injections of mercurochrome, arsphenamine and antimony and potassium tartrate have been previously tried by the author in cases of brucella infection with no obvious benefit

Raw Spleen Extract in Tuberculosis—Watson discusses the results obtained in experiments with injections of raw-spleen extract carried out during the last four years on guinea-pigs The general procedure has been to inoculate the animals with an emulsion of tubercle bacilli subcutaneously in the right groin and to treat them with subcutaneous injections of spleen extract in the left groin Forty eight guinea-pigs were divided into two groups of equal weight One group was given two preliminary doses of spleen extract and nine days later was inoculated with tubercle bacilli The treated series were given 0.375 cc of spleen extract every second day Sixty-five days after inoculation, four treated and twenty one untreated animals were dead Each guinea-pig in both series was examined post mortem and showed generalized tuberculosis Other experiments gave similar results

Renal Function Tests—Urquhart and McCollum performed a series of 113 clearance tests on seventy eight patients In addition, concurrent blood urea and nonprotein nitrogen determinations have been obtained in the whole series In a small group divided phenolsulphonphthalein tests have been carried out in conjunction with the other determinations The usual technic was followed throughout No practical advantage was found in the use of the micromethod of Conway and Byrne for blood and urine urea Repeated blood urea nitrogen determinations were found to be as efficient from the standpoint of prognosis as repeated urea clearance determinations The degree of kidney damage demonstrated by moderately subnormal clearances did not prove to be an appreciable factor in the operative risk In the group with very low clearances and consequently poor kidney function the repeated blood urea nitrogen determinations and the clinical state of the patient gave ample warning of impending danger The deaths in the series were almost evenly divided between renal and extrarenal causes The renal deaths were for the most part preoperative, and surgery was not attempted because of the condition of the patients The divided phenolsulphonphthalein test is of value in the estimation of the kidney function It gives results comparable to the urea clearance and is perhaps more adaptable in a general hospital In common with the other tests, it is the direction of change in successive tests that is of significance from the standpoint of prognosis rather than the individual test itself

Incidence of Duodenal Diverticula—Of the 133 cadavers examined for duodenal diverticula Grant found fifteen that had single or multiple diverticula None of the ten subjects between 17 and 32 years of age had diverticula, one of the twenty between 33 and 42 years and one of the twenty-one between 43 and 52 years had diverticula Four of the twenty-six subjects between 53 and 62 years, five of the thirty between

63 and 72 years, fourteen of the nineteen between 73 and 82 years and none of the seven more than 82 years had diverticula. Of these subjects thirteen were male and two were female. For each decade after the fifty-second year the proportion of duodenums with diverticula remains almost constant, at about 15 or 6, whereas before this period the proportion is about 1255. Of the fifteen specimens with diverticula, eleven had one, three had two and one had three, making twenty diverticula in all. All save one sprang from the concave, pancreatic border of the duodenum, and all save this one were buried in the substance of the pancreas, and, had the duodenum not been filled with wax, a number of them would certainly have escaped detection. From the junction of the first and second parts of the duodenum there was one diverticulum. From the second part there were fourteen, of these, eight arose around the entrance of the common bile and pancreatic ducts (perivaterine). From the junction of the second and third parts there were two diverticula, and from the third and fourth parts there were three. Though the diverticula were not sectioned and examined microscopically, it was in most instances apparent with the aid of a lens and probe that these diverticula were of mucous membrane herniated between the fibers of the circular and longitudinal muscle coats, which sometimes were carried on to the neck of the sac for a few millimeters. The specimen springing from the convex border of the second part was also of this nature.

Treatment of Empyema in Children by Aspiration—Burpee discusses the twenty-six cases of empyema in infants treated by aspiration. Twenty of the patients were cured by aspiration without an operation. Four of the patients were later operated on with no deaths. The mortality in the group was 76 per cent. The patients ranged in age from 5 months to 12 years. The pneumococcus was the organism present in 60 per cent of the cases and in all the cases that later required open drainage. The staphylococcus was the organism present in 11 per cent and the streptococcus in 55 per cent. In 55 per cent the pus was sterile. The average number of aspirations was ten and the average stay in the hospital was sixty-one days. In a few cases small subcutaneous abscesses developed that were drained, otherwise no complications developed. Permanent deformity was not observed.

Roentgen Differentiation of Osteomyelitis and Bone Tumors—Jenkinson believes that, in the differentiation of neoplastic from inflammatory lesions, it is imperative that the roentgenologist obtain all the information that can be elicited through a complete history including laboratory observations. The salient points in the roentgen diagnosis of inflammatory lesions are 1 Infections usually occur in young people, probably more frequently in men than in women 2 The infection occurs more frequently during the active period of a person's life when he is exposed to injury. The infection does not always start from an external wound, but the injury often causes a lowered resistance of the part, and the infection localizes at this point 3 The first roentgen examination may reveal no evidence of pathologic changes in the bone. It is inadvisable to take a negative report from the roentgenogram as final, especially if the examination has been made within the week. Usually, roentgen changes in bone infections are slow in presenting themselves, and they do not become manifest until a week or ten days after the infection. The first change usually reported is bone rarefaction due usually to destruction, but, if the roentgenogram is examined closely with a magnifying glass, the earliest observation is an area of increased density probably due to edema and infiltration of leukocytes. An inflammatory process may attack large portions of the bone, but usually the lesion is not as extensive as neoplastic lesions. It is much more difficult to differentiate primary bone tumors from inflammatory lesions than it is to differentiate metastatic tumors from bone infection. Whether a lesion is malignant or benign is often judged on the roentgenographic appearance by the nature of the bony changes—osteoporoses, osteosclerosis, erosion, new bone formation. Lesions that show a mass extending from the bone into the soft tissues are neoplastic and not inflammatory. In the early acute stage of osteomyelitis, there are usually no visible roentgen changes, and the diagnosis or the operation should not be defined on roentgenographic evidence. As the lesion becomes chronic, proliferation of new bone appears and areas of new bone can be seen in the area of destruction. In chronic osteomyelitis, localized abscesses often develop. These abscesses usually occur in the ends of long bones and occasionally they develop in the body of a vertebra. The complete removal of a large piece of cortex may simulate bone invasion, which is an important diagnostic point between osteomyelitis and neoplasia.

Tuberculin Test in Diagnosis of Ocular Tuberculosis

—Friedenwald and Dessoiff observed that of ten cases of proved ocular tuberculosis six reacted to 0.001 mg of tuberculin, while only one failed to react to all dilutions below 1 mg. The proportion of strongly positive reactions in this group is much higher than in the general population. Extreme hypersensitivity to tuberculin is therefore of definite diagnostic significance in these cases. Moderate hypersensitivity to tuberculin producing reactions to 0.1 or 0.01 mg is no more common in cases of proved ocular tuberculosis than in cases of nontuberculous uveitis. No diagnostic significance can therefore be given to this degree of reactivity in relation to the ocular inflammatory condition. Finally, an essentially negative reaction to tuberculin can occur even in patients with active ocular tuberculosis. Such a negative reaction cannot therefore be taken as conclusive evidence that the ocular lesion is not tuberculous. Hence the significance of the intracutaneous tuberculin test can be evaluated only when weighed in relation to all other clinical data.

The Parathyroids and Vitamin D.—Jones states that young growing pups fed a modification of the Karr Cowgill diet for dogs, to which had been added 0.75 per cent beryllium carbonate, developed a severe rachitic condition in a few weeks. Neither direct ultraviolet irradiation of the animals nor the administration of cod liver oil prevented the onset of the disturbance. Large doses of parathyroid extract failed to produce any marked rise in the level of calcium in the serum of the beryllium fed animals, even though vitamin D was administered. Viosterol, given in daily amounts of 150,000 international units per kilogram of weight readily produced a marked hypercalcemia with toxic symptoms in the animals which failed to

respond to parathyroid extract. From the data presented it appears that the failure of rachitic animals to respond to parathyroid extract is not directly due to a lack of vitamin D. Furthermore the toxicity of viosterol is not due to a stimulation of the parathyroids.

Tests for Immunity to Acute Anterior Poliomyelitis

—Since they found that monkey serum neutralization tests are of limited application, Kolmer and Rule have inquired into the possibility of employing serum colloidal gold, complement fixation and precipitation tests for the detection of immunity to poliomyelitis and they briefly summarize the results. The serum colloidal gold test is not acceptable as a substitute for the monkey serum neutralization test for poliomyelitis antibody. The complement fixation test employing antigens of monkey poliomyelitic spinal cord gave completely negative reactions with the serums of human beings containing antiviral antibody. The serums of normal and poliomyelitic immune monkeys gave completely negative Wassermann reactions. The serums of normal monkeys gave completely negative complement fixation reactions with antigens of monkey poliomyelitic spinal cord. Some of the serums of monkeys with poliomyelitis, as well as some immunized with poliomyelitis vaccine or previously inoculated intracerebrally with neutralized serum-virus mixtures, gave positive complement fixation reactions. All the human and monkey serums employed in the complement fixation tests gave completely negative precipitation reactions with an antigen of monkey poliomyelitic spinal cord.

Gonococcus Complement Fixation Test.—Thomson and his associates point out that the value of the gonococcus complement fixation test as an aid in the diagnosis of gonococcal infection is lessened because of the irregularity of reports on the same serums from different laboratories. This irregularity has been overcome by considering the hemolytic and binding power of the complement in one test. The Hamann combined system largely removes the irregularities previously noted in the diagnosis of serums sent to different laboratories. It consists in recognizing and titrating the fixing and hemolytic power of the complement. Previously the complement was tested solely for its hemolytic power.

Surgical Maggots—Messer and McClellan state that chronic osteomyelitis wounds healing in the presence of blowfly larvae develop reactions more alkaline than pH 7.4 in contrast to wounds dressed only with physiologic solution of sodium chloride. Sterile larvae of *Lucilia sericata* produce sufficient ammonia to account for this excess alkalinity. The excess alkalinity is probably a factor in bacteriostasis and wound healing. Blowfly larvae excrete a relatively weak proteolytic enzyme, while they contain in their digestive tract a more powerful one. The relative strength and location of these enzymes permit the removal of necrotic tissue from a wound with a minimum of irritation. The assimilation by the larvae of the protein split products of necrotic tissue removes the latter from the wound, in which they would otherwise putrefy or be absorbed to the detriment of the patient. Maggot therapy depends for its beneficial action on the presence of living larvae, which cannot be successfully replaced by pastes or extracts of maggots.

Carotene, Vitamin A and Diabetes Mellitus—Ralli and her associates found the fasting blood carotene to be higher in eight of nine patients with diabetes mellitus than in a group of nine nondiabetic subjects. Following the administration of carotene in oil and of carrots, the blood carotene rose sooner in the diabetic patients and the increase was greater and was maintained for a longer period of time. A second administration of carotene to nondiabetic persons did not result in any greater increase in the blood carotene than did the first dose. In the diabetic patients a second dose of carotene caused a greater increase in blood carotene in all but one case. To obtain a curve in a normal person simulating that in the diabetic patients, it was necessary to administer large amounts of carotene. The prolonged administration of 1 cc of carotene in oil to three normal and three diabetic patients resulted in a greater increase in the blood carotene in the diabetic patients and a more gradual fall. The fasting blood cholesterol was higher in the diabetic patients but bore no absolute relationship to the height of the blood carotene. The blood sugar bore no relationship to the blood carotene. To explain these results the authors advance the hypothesis that there is an increased concentration of carotene present in the liver of patients who have diabetes, owing to a diminished ability on the part of this organ to convert carotene to vitamin A, and that this increased concentration of carotene interferes with the absorption of carotene from the blood.

Sodium Ricinoleate in Treatment of Varicose Veins.—Froehlich and Henrikson used sodium ricinoleate, prepared in accordance with the directions of Rider, as a sclerosing agent in the treatment of varicose veins. A history is obtained, drawings of the veins are made on charts and a urinalysis is done. If there are no contraindications, 1 cc of sodium ricinoleate is injected in a small loop of vein in the lower leg, as a test to see whether the patient has any idiosyncrasy to the solution. With sodium ricinoleate the only reactions in a series of 300 cases have been those in which irregular purplish red blotches varying in size from 2 to 20 mm appeared on the skin drained by the offending vein. In two patients these patches took the form of a localized urticaria. However, there were no subjective symptoms. A cramping pain in the lower leg and foot is sometimes experienced when 5 cc. doses are used. The patient returns for a second injection in two or three days when from 3 to 5 cc is injected at the highest point possible. The needle on an empty 2 cc syringe is inserted into the vein while the patient sits on the edge of a table. Then the patient lies down and the leg is elevated to drain as much of the blood from the vein as possible. The small empty syringe is replaced by one containing the solution, without moving the needle. The injection is made, the operator watching for evidences of perivascular injection. A tourniquet is applied near the groin. The syringe is removed, with the needle left in place. The patient is asked to sit up with the leg hanging down. This change in position gives the solution a chance to gravitate downward. The tourniquet is removed in from three to five minutes. The needle is then withdrawn and a small compress is taped over the site of injection. By this method the authors have often been able to sclerose the veins of an entire leg by two or three injections. It is their opinion that ligation of the saphenous vein in the groin greatly decreases the possibility of recurrence in those patients having large varicosities extending into the thigh. Under local infiltration of 2 per cent solution of procaine hydrochloride, the vein is exposed through a 5 to 10 cm incision. A small section is excised and the cut ends doubly ligated, chronic catgut

number 1 being used. Then from 3 to 5 cc of the sclerosing solution is injected into the exposed distal stump and the skin is closed, with dermal or skin clips. The patient is allowed to go home at once, and may be up and about as desired. Should the leg become painful, hot applications are advised. All patients treated should be checked for recurrences at intervals of from two weeks to two months for a year.

Relation of Thymus Gland to Surgical Risk.—According to Henson, children who have had thymic symptoms or who show definite or indefinite evidence of thymic enlargement are better not operated on but, if operation is essential, should have a course of roentgen therapy previous to that procedure. Adults who exhibit the characteristic signs and symptoms of the lymphatic condition should never be operated on unless it is necessary for the maintenance of life. Nesbit has presented evidence which seems to indicate that in the lymphatic condition there is a reduction in the function of the parathyroids, and consequently low serum and spinal fluid calcium. Roentgen therapy raises the calcium content of these fluids and probably exerts its beneficial effects in this manner. The same result may be obtained by the intramuscular injection of parathyroid extract combined with the oral administration of calcium gluconate.

Prophylaxis of Measles.—Karelitz points out that in the evaluation of passive immunity to measles by the use of convalescent serum, immune adult blood or serum and more recently, globulin, extracted either from human placentas or from immune adult blood serum the dosage depends on the consideration of age size and physical state of the exposed individual, the duration and intimacy of the exposure and the period that has elapsed since the first moment of the exposure. The age and period of exposure have been considered in most studies, but it has only recently, been demonstrated that other

conditions, the epidemiologic factors, were vital in evaluating a measles prophylactic measure. Thus the author believes that hospitals, nurseries, schools and so on are not suitable for measles prophylaxis studies, since under such conditions the degree of exposure of the children must vary, and the certainty of exposure of all susceptibles can never be established. In studies conducted in homes, in which the contact between the sick and susceptible children was intimate and long, the percentage of complete protections was smaller, unless the serum dosage was increased. In homes in which better hygienic conditions prevailed the serum used seemed to be more effective than in homes of poor hygiene but less effective than in hospitals, nurseries and other such institutions. It is evident that, unless all these factors are considered by all workers, no uniform results will be obtained. The literature demonstrates just that. Except in the use of convalescent serum, the results are difficult to interpret in most reports.

Traumatic Subdural Hematoma.—Gardner discusses twenty-two typical cases of subdural hematoma. Only two patients were women. Two thirds of the patients were more than 40 years of age. The preponderance of these lesions in older patients must be explained by the lessened elasticity and greater fragility of the cerebral veins, which develop with advancing age. Chronic alcoholism was not a predisposing factor. In only six cases was the blow to the head of sufficient force to cause unconsciousness. In no case was there roentgenographic evidence of a fracture of the skull. It is inconceivable that a tear of the cerebral veins is more common after a mild trauma than after a severe one. In two thirds of the cases the patients either maintained or assumed the erect posture immediately after the accident and in only two cases were they definitely known to lie down. The author can advance no reason why the erect posture following cranial trauma should favor venous bleeding unless it could be because of a lowering of the arterial and a rise in the venous pressures secondary to partial syncope. On the other hand, in cases of severe cranial trauma the maintenance of the horizontal position the occurrence of cerebral edema, the laceration of the membranes and the presence of a fracture seem to militate against the formation of a large subdural clot, or, if one has formed one or more of these conditions may predispose to its absorption. The force of the blow was exerted in an anteroposterior direction, that is it was received on the frontal or occipital regions in fifteen cases on the side of the head in three cases, on the vertex in two cases and in two cases the site was not known. The average time interval between the trauma and the operation (or necropsy) was twelve and a half weeks. The shortest interval was five weeks and the longest was thirty three weeks.

When the interval is much longer than this, it would appear likely that the implicated trauma is not the responsible one. Headache was the chief complaint in nineteen cases, and alterations in the intellectual sphere as shown by confusion, somnolence and personality changes were frequent observations. Somnolence, when present, was out of all proportion to the degree of intracranial pressure. The most stuporous patients frequently had a normal or subnormal spinal fluid pressure. Vomiting occurred in seven cases, vertigo and visual complaints each in three instances. The neurologic observations indicated the side of the lesion in eight cases. In five there were no localizing signs. In five the neurologic signs pointed to the wrong side of the head and in four patients with unilateral lesions the neurologic signs indicated bilateral damage. Two patients exhibited a homolateral homonymous field defect. This rare observation must be associated in some way with the marked dislocation of the brain occasioned by these large lesions. It could be explained by pressure on the optic radiations in the region of the lateral geniculate by the margin of the incisura of the tentorium. In the four cases in which there were hematomas on both sides, no localizing signs were present. A definite choking of the optic disks was present in three cases, a mild edema in three cases, a haziness of the disk margins in four cases, and in twelve instances the disks were normal. Spinal puncture in twenty cases revealed a normal or subnormal pressure in twelve instances and an increased pressure in eight. In thirteen cases the spinal fluid was xanthochromic and in seven it was colorless. Twelve patients treated by formal craniotomy recovered. In eight patients the operation consisted of a simple drainage of the lesion through a cranial perforation, two died, but the type of operation was not responsible for the deaths. In both instances there were bilateral lesions. The other six patients treated by simple drainage recovered as quickly and completely as those treated by craniotomy and complete evacuation. In none of these cases was an attempt made to remove any part of the wall except that immediately beneath the craniotomy opening. Since drainage through a single opening has proved satisfactory, through and through drainage by means of two openings as advocated by Fleming and Jones was not employed. Of the eighteen patients who recovered, fourteen were restored practically or entirely to their former state of health.

Periodic Human Microfilaria in the Philippines—The results of Africa and his co-workers tend to indicate the existence of the periodic type of microfilaria (microfilaria of *Wuchereria Bancrofti*) in the Philippines, contrary to allegations in textbooks in the general literature. They do not discount the presence of the nonperiodic type, as suggested by the results of the investigations of Ashburn and Craig (1907), although, judging from the observations of more recent workers, the former is the more prevalent type in this country. The duality of the microfilarial type in the Philippines seems to be supported by the ethnic origin of the Filipino race and by the

immigration of people into that country from the Asiatic mainland, which has been going on for centuries. The authors' results would also indicate that the best time for obtaining blood for diagnostic purposes is between 10 p. m. and 2 a. m. However, a negative count in the presence of clinical manifestations is without value, since it has been demonstrated repeatedly in numerous surveys that in a large number of cases of actual filarial infection, in some of which living adult females were demonstrated, no microfilariae could be demonstrated in the blood.

The Allergic Child.—Regarding the treatment of asthma in children, Petersen states that it is in a large majority of cases dependent on a sensitiveness to the bacterial proteins of the child's chronic and recurrent respiratory infection and can be stopped if the child can be made relatively immune to his own respiratory flora. The most successful means for accomplishing this is by the use of an autogenous vaccine in graduated doses over a period of months of intensive treatment and years for occasional inoculation with the same vaccine.

New Procedure for Lumbar Puncture—Reese and Shulak recommend giving the patient 50 cc. of a 0.225 hypotonic solution of sodium chloride from five to ten minutes before the spinal puncture is performed. After the spinal puncture is performed, the patient is kept quiet for one hour and then allowed to get up. The postpunctural headaches in their group of twenty-five patients were completely eliminated by this new method. Only one patient complained of a slight frontal headache lasting for approximately eight hours. It is difficult to say in this instance whether the headache was the result of the spinal puncture or whether it was merely a manifestation of excessive indulgence in alcoholic beverages. In order to demonstrate whether hypotonic solution of sodium chloride is of therapeutic value after postpunctural headaches have occurred the authors performed lumbar punctures without giving the preliminary injection and then allowed the patients to get up and walk about one hour thereafter. As soon as postpunctural headaches occurred, 50 cc. of the solution was given intravenously. With this procedure the responsive improvement was variable. Some patients were definitely benefited, the headaches disappearing approximately one-half hour after the injection of the hypotonic solution. Another group of patients showed response to this procedure in that the headaches were not as intense as before the injection and the duration of the headaches was definitely shortened. A few, however, showed no appreciable response to this treatment, the headaches continuing even after the injection. The best results were obtained when the hypotonic solution was given from five to ten minutes before the spinal puncture.

Cleidocranial Dysostosis in the New-Born.—Higgins states that cleidocranial dysostosis manifests itself in delayed development of the membranous bones of the skull and clavicles. It may or may not be hereditary, while deformities of the spine, scapulas, thorax, pelvis and limbs may also occur. In his case, a new-born child, the last of a family of five, showed an absence of the right clavicle and of a portion of the left clavicle and a marked bone deficiency of the skull. The cause of the condition is not known. Amniotic bands, injury, hereditary tendencies, germinal abnormalities and arrested development have all been advanced as possible causes. It would seem, however, that the true cause may be found in the theories of Fitzwilliam and Couvelaire, who suggest that the condition is probably due to the absence of certain chemical constituents that are normally present and are necessary for the calcification of membranous bones. Differential diagnosis should present no great difficulties as a rule, though special attention may be required when anencephaly, intra-uterine fractures and fractures at birth are dealt with. There is also a medicolegal aspect of some importance.

Prevention of Compressed Air Illness.—Boycott states that the fact that strict stage decompression has been adopted for divers in the navies of the United States and of France, examples of whose rules for decompression for caisson and tunnel workers have been given, seems sufficient proof that the stage method is the method most approved by physiologists in

these two countries. There remains, therefore, only the existence of obsolete state regulations to account for the fact that stage decompression has not been adopted for caisson and tunnel workers in France, and in only a modified form in the state of New York. With small airlocks compromise methods may be necessary or even desirable. But it seems clear that, in the sphere of compressed air work, state regulations have proved to be more of a hindrance to health than a help to those for whose benefit they were intended.

Virulence and Immunogenic Activities of *Bacillus Typhosus*.—Felix and Pitt observed that rough variants, derived from strains of *Bacillus typhosus* which possess the Vi antigen may still contain this antigen though the smooth O antigen has been lost. Such variants, which are nonvirulent, are yet capable of inducing active and passive immunity. The virulence of *Bacillus typhosus* depends on the combined activity of the smooth O and the Vi antigen. Nevertheless the Vi antibody alone is sufficient to protect against infection with strains of the highly virulent type. The use of avirulent, rough, but Vi-containing variants as vaccines and in the preparation of therapeutic serums is discussed. Large doses of a live vaccine of this avirulent culture could be inoculated into horses without those harmful effects that follow the injection of the smooth virulent bacilli in the living state. The Vi antibody in the serum of rabbits and horses immunized with this rough variant was found to be as potent in protective action and in its phagocytosis promoting activity as was the Vi antibody derived from immunization with the smooth and highly virulent bacilli. The efficacy of a therapeutic antityphoid serum also depends on the presence in it of an adequate amount of the O antibody, which is responsible for effecting the neutralization of the endotoxin of *Bacillus typhosus*. This antibody can be produced by injecting a dead vaccine containing the smooth O antigen, whereas the live rough variant serves as the source of the "natural" Vi antigen required for the elaboration of the Vi antibody.

- *Observations on Certain Aspects of Cyclic Vomiting Syndrome. L. Dods—p. 231
- Vitamin C in the Australian Fauna. G. Bourne—p. 260

Cyclic Vomiting.—Dods states that an investigation of ketonuria among 685 admissions revealed a general incidence of 46 per cent, an incidence of 57 per cent in the febrile and of 30 per cent in the afebrile children, and a lower incidence in the group of children less than 3 years of age. Attempts to assess the part played by either emotional disturbances or marked physical exertion in the production of ketonuria proved inconclusive but suggested that these stresses, unless unduly severe or prolonged, would be unlikely to produce ketonuria in the normal child. As the result of a clinical study of eighteen children subject to attacks of cyclic vomiting, the majority of which were observed over a period of about two years, it was observed that cyclic vomiting was more common among the outpatient class, there was frequently a family history of similar attacks, the majority of the children were alert and easily excitable, defects of stance and signs of vasomotor instability were frequently noted, the first attack usually occurred between the ages of 3 and 8, the majority of the attacks commenced during the night or the latter part of the day, the dramatic and sudden recovery from even prolonged vomiting was a striking feature of many attacks, the degree of ketonuria encountered during an attack frequently failed to bear any direct relation to the gravity of the attack, in a small group of these susceptible children mild acute infections and short anesthetics did not precipitate attacks and the possibility was suggested that undue emotional disturbance or undue emotional and physical stress may aggravate or precipitate the underlying metabolic disturbance in the susceptible child. This disturbance might be defined as the clinical picture of the overtired child. This syndrome of overtiredness has many features in common with the early stages of cyclic vomit-

ing and usually occurs in the same highly sensitive type of child. Ketosis alone apparently is not the cause of cyclic vomiting but is probably a concomitant of the unknown underlying disturbance. Attacks of spontaneous hypoglycemia in childhood may closely simulate cyclic vomiting. In a small series of normal and cyclic vomiting children, blood sugar levels were found to be slightly lower in both groups of children during ketosis, and the blood sugar showed a normal response to the subcutaneous injection of a small dose of epinephrine. Prophylactic dietaries (prolonged) given to two groups of cyclic vomiting children supported the fact that the group whose fats were carefully restricted and whose diet consisted mainly of carbohydrates did not show any better response than those children who were given adequate fat and an ordinary amount of carbohydrate. If the susceptible children were protected as much as possible from emotional stresses there was a definite diminution in the number of their attacks. A short but complete rest, and possibly some nerve sedatives before and/or after any unavoidable stresses of this nature seemed to be helpful in aborting possible attacks.

Albuminuria in Adolescence—Bashford points out that evidence from the records of the medical branch of the post office appears to support the view that adolescent albuminuria, alone, and in the absence of any other signs or symptoms, is a nonpathologic, idiosyncratic condition of neither immediate nor potential significance. In the great majority of cases the after-returned specimens are free from albumin, though not in all nor at all times. It is probably wise, in the present state of our knowledge, to regard the small minority, in which the presence of albumin is constant in all specimens, with rather more care from an insurance point of view. But there seems little doubt that a certain number of these also belong to a nonpathologic and idiosyncratic type, and if, in these cases, there is satisfactory evidence of general renal efficiency, there would seem to be no reason to think otherwise. About one in every twenty young male adolescents and at least the same proportion and perhaps more of young female adolescents will be found to show this condition. In a considerable number of instances it may persist for many years, if not throughout life. The condition is not associated with any particular physical type or build of young man or young woman, or with lordosis, ovaluria, a history of scarlet fever or a history of general nervous instability. It is without significance in respect of either current or future ill health.

Acute Infectious Diseases at School—Smith warns that schools are not immune from any infections. Recently epidemics of rheumatic fever, catarrhal jaundice and bacillary dysentery have been reported. Influenza is of paramount importance, over which there seems to be little control. The following policy should be considered by those who are responsible for the care of children. 1 Whooping cough vaccine in sufficiently large doses should be given at an early age together with a suitable diphtheria prophylactic, preferably toxoid-antitoxin floccules. There seems no contraindication to mixing the vaccine with the toxoid-antitoxin floccules. Benson advises mixing the prophylactics in active immunization against scarlet fever and diphtheria. 2 Measles and whooping cough should be vigorously prevented or arrested until after the age of 5. If contact with measles has occurred and an attack is almost

inevitable, serum should be given and attenuation achieved if possible. The provision of measles serum on a wide scale and facilities for bacteriologic diagnosis of whooping cough are matters of great importance and some urgency. 3 Unnecessary waste of time and inconvenience should be avoided by allowing contacts with measles, mumps, chickenpox and rubella to return to school provided they have been kept away from the source of infection as soon as it was recognized.

 *Presence of Carotene in Ovarian Tumors Report of Case. C. Y. Ch. P L Li and C. S. Yang—p 751

Presence of Carotene in Ovarian Tumors—Chi and his associates discuss a case of dermoid cyst of the ovary combined with pseudomucinous cystadenoma, which resulted in peritoneal implantations. This condition is generally known as pseudomyxoma peritonei. In the combined cystomas the mucinous material is usually mixed with fatty materials. The fluid contents of such tumors may be colorless or brownish; the latter color is probably due to the presence of altered blood pigment. Discoloration of the fluid by carotene is almost unknown in the literature. According to Anzei its absorption in the intestinal tract takes place by virtue of its solution in fat. Lipoid substances in general have a great affinity for carotene. High blood carotene content is frequently observed in cases of diabetes mellitus with increased blood cholesterol. Carotene excretion is effected through the sebaceous and sweat glands of the skin and through the epithelial cells of the kidney tubules. Opinions differ in regard to its excretion through the skin. Hashimoto holds that its excretion is carried out mainly by the sebaceous glands of the skin, while Anzei insists that it is excreted only through the sweat glands. In two cases Anzei found at necropsy marked yellow pigmentation in the subcutaneous omental and mesenteric fat tissues. Other organs, such as the kidneys and the adrenals, were also intensely pigmented. It is evident therefore that carotene may be retained by any fatty tissues of the body. Since the fluid content of this tumor is rich in fatty material from the sebaceous glands and degenerative products of the squamous epithelium, carotene is present in greater concentration in the cystic fluid than in the blood.

Blood of Hypertensive Patients—Carrière and his collaborators made studies of the blood of 105 hypertensive patients with a view to determining the principal physicochemical properties of the blood and their possible relations to one another. From the physical point of view the blood of all permanent hypertensive patients is characterized by increased weight by hyperviscosity of the blood and to a lesser degree of the serum and by considerable increase in the osmotic pressure of the serum. The uremia of hypertensive patients is moderate except in cases of gross renal lesions. The plasma chlorides are generally low. The sugar metabolism appears little disturbed as a rule. A slight but constant disturbance of protein metabolism is present. This is shown by a moderate hyperproteinemia and especially by an elevation of the albumin-globulin quotient. It is certainly the fat metabolism that is modified most by the hypertensive process. The hypercholesterolemia is considerable and constant. These observations are presented in the words of the authors "independently of all premature pathogenic interpretation."

Pyrogenic Principle in Human Urine—Urechia and his collaborators investigated the fever-producing properties of urinary residues obtained from various sources. The residue was prepared by evaporation of the urine to dryness in a vacuum. The residue thus obtained was kept in a dryer with calcium chloride. Finally it was dissolved in distilled water at the ratio of 0.1 Gm to 1 cc. of water. The quantity injected in rabbits varied from 0.1 to 0.6 cc. Later similar preparations obtained from the urine of patients with dementia praecox were used in dementia praecox and in dementia paralytica by the intravenous route. In practically all instances a considerable febrile reaction occurred. This was frequently associated with marked clinical improvement. Intradermal tests with the urinary residue, practiced on patients with dementia praecox, dementia paralytica, parkinsonism and manic-depressive insanity as well as on normal persons, produced no reactions. The urine of normal persons contains a chondromucoid substance that is found in greater quantities in certain conditions, such as dementia praecox, dementia paralytica and pregnancy. The urinary residue obtained from these sources possesses a strong fever producing action, while that from normal persons or persons having tuberculosis, myopathy or cancer is much less active.

- *Dimethyl Carbamic Ester of Hydroxy Phenyl Tri Methyl Ammonium Methyl Sulphate the Physostigmine Derivative in Treatment of Postoperative Intestinal Obstruction E. Pescarmona.—p 1899
- Acute Febrile Syphilis Case V. de Antoni.—p 1906
- Orchitis and Orchiepididymitis in Brucellosis and Other Infections D. A. Mazzolani.—p 1912

Treatment of Postoperative Intestinal Obstruction—Pescarmona advises the use of dimethyl carbamic ester of hydroxy phenyl-tri-methyl ammonium methyl sulphate the physostigmine derivative, injections in the amount of 1 cc. of a 0.5 per thousand isotonic stable solution at each injection

that is, 0.0005 Gm of the active substance in 1 cc. of the solution, in the treatment of postoperative dynamic intestinal obstruction. This treatment gives satisfactory results even in cases in which the ordinary methods of treatment, such as enemas the use of a rectal sound, intravenous injections of hypertonic salt solution and hot cataplasms, have failed. It does not produce harmful effects on the heart or on the arterial pressure, or clinical complications of any sort. The abdominal pain with which some patients react is transient and tolerable. As a rule one injection of the mentioned dose is sufficient to obtain satisfactory results. Nevertheless, in severe cases one may give two or more injections (up to five or six) at intervals of a few hours during the same day without any danger to the patient and usually with good results. Although the injections may be given either intravenously or intramuscularly, the latter technic is preferable because of its simplicity.

Semana Medica, Buenos Aires

- *Intradermal Infiltration in Treatment of Leprosy S. Schujman and J. M. M. Fernández.—p 790

Extraperitoneal Cervicosegmental Cesarean Section—Leon states that extraperitoneal cervicosegmental cesarean section according to Michon's technic gives better results than transperitoneal segmental cesarean section in labor complicated by amniotic infection, either proved or suspected. The refinement of Michon's technic consists in the utilization of portions of the peritoneum for exclusion of the operative field through coaptation of the visceral and parietal edges of the peritoneum at the line of transversal peritoneal incision by means of sutures or forceps. This is followed by the cervicosegmental longitudinal incision, extraction of the child, administration of an intramural injection of a pituitary preparation in order to promote spontaneous expulsion of the placenta, suture of the muscular wall of the uterus, removal of the forceps or sutures and in infected cases, insertion of a Mikulicz drain. The author's modification consists in covering the peritoneal flaps with impermeable compresses, which are fastened on one side to the peritoneal edges and on the other to the border of the cutaneous laparotomic incision, thereby excluding the hysterotomy field from the peritoneal cavity and protecting the latter, as well as the hypodermic cellular tissues, against contamination with the amniotic fluid. The author performed cesarean section according to Michon's technic in five cases. Impermeable compresses were used in three cases of the group. The peritoneal flaps were lacerated in two cases, with and without impermeable compresses, respectively. Neither amniotic fluid nor blood was found in the peritoneal cavity or in the cellular hypodermic tissues in the case in which the structures had been protected by an impermeable compress. A drain was left in these two patients and also in a patient with amniotic infection. The incision of the inferior segment of the uterus was peritonized in four cases. As a whole, the postoperative period was uneventful, peritoneal reactions did not develop, and in time both mothers and children left the hospital in satisfactory condition.

Intradermal Infiltration Method in Treatment of Leprosy—Schujman and Fernandez state that intradermal infiltration of chaulmoogra derivatives is the most active method for the treatment of leprosy. Not all chaulmoogra derivatives can be given by the intradermal route because of the severe local reaction they cause. Tattooing and the intense local reaction that follows the infiltration are the most serious results of the treatment. A chaulmoogra derivative that would cause neither tattooing nor intense local reactions when intradermally injected would be the ideal preparation for the method of intradermal infiltration.

*Value of Kline's Microscopic Slide Precipitation Test for Serodiagnosis of Syphilis J Schmitz—p 1320

Action of Digitalis in Paroxysmal Tachycardia—Aschenbrenner agrees with Bohnenkamp that the customary treatments of tachycardia are comparatively unreliable, pointing out that even the most commonly employed intravenous injections of quinidine fail in severe cases. Moreover, quinidine is not entirely harmless in patients with heart disease, for the author detected considerable changes in the electrocardiogram following its administration. Bohnenkamp obtained favorable results in severe attacks of tachycardia by the intravenous injection of large doses of digitalis. Because patients with mitral stenosis are ordinarily susceptible to digitalis, the author reports a case with paroxysmal tachycardia and mitral stenosis. In a severe attack of tachycardia, when, in view of the mitral stenosis, the life of the woman seemed in danger, the author decided to follow Bohnenkamp's suggestion to administer a large dose of digitalis. The results were satisfactory. When three weeks later the patient had another attack of tachycardia, she again was given an intravenous injection of a large dose of digitalis. She developed anginal pain and vomiting, but these symptoms disappeared after the tachycardia had been brought under control. The author thinks that it is especially important to produce a prompt interruption of the tachycardia in mitral stenosis. He says that the intravenous administration of doses corresponding to from 0.45 to 0.5 Gm of digitalis leaves caused, in addition to severe vomiting, only slight signs of intoxication, which subsided again in from one to three days.

Kline's Precipitation Test for Syphilis—Schmitz describes his experiences with this test employed on 2,100 specimens of serum and on 187 specimens of cerebrospinal fluid. He compared its reliability with that of the Wassermann, the Kahn, the Meimcke turbidity and the Meimcke clarification tests. He reaches the conclusion that the Kline test is a valuable method in the serologic demonstration of syphilis. As regards its sensitivity and specificity, he found that it takes an intermediate position between the turbidity and the clarification tests of Meimcke. He thinks that few syphilitic serums will escape detection even if the Kline test is the only serologic method employed. The advantages of the Kline method that make it particularly valuable for serial examinations are its rapidity and the economic use of materials, for the test can be made with 0.05 cc of serum and 0.008 cc of dilute antigen. The author thinks that, if it is used for routine examinations on large numbers, the positively reacting serums may then be subjected to other serologic tests.

Surgical Therapy of Adherent Pericarditis—Winkelbauer and Schur describe eight cases of adherent pericarditis and recommend the following principles for the surgical treatment. If the stasis in the inferior cava predominates, the site of anastomosis of the inferior cava should be liberated, but, if hydrothorax is the most prominent symptom, it is important

to free the left ventricle. It should be taken into consideration that some of the anatomic changes are compensated by an improvement of the cardiac function. The improved function is facilitated particularly by freeing the heart from the diaphragm and from the adhesions on the posterior wall. The decortication of the right ventricle (anterior surface) is much less important. It is inadvisable to complete the operation in one stage. Since the condition of the myocardium is the decisive factor for the extent of the operation, the electrocardiogram and the peripheral edemas have to be given careful attention. If the myocardium has already become considerably impaired by a growing in of the adhesions, completion of the operation in one stage is impossible. In severe cases of this nature the first stage of the operation consists only in Brauer's cardiolysis. In cases of myocardial lesion in which the condition of the patient permits it the curass may be broken at the same time by an incision above the left ventricle, and further decortication can then be done by a second or third intervention. During the operation the blood pressure and the pulse should be constantly watched, and it is advisable to interrupt the operation as soon as there are signs of diminution of the heart action. If the indurated tissue contains calcareous plates, especial precaution is necessary, if there is complete adherence between the pericardium and the epicardium or if the calcareous plates are in the epicardium, it is better to refrain from removing the plates, for it may prove impossible to close a perforation of the ventricle. In these cases the decortication should be limited to the uncalcified regions. In view of the fact that considerable functional improvement is often obtained merely by removing the bones of the thoracic wall (cardiolysis), it is advisable not to resort immediately to a transpleural intervention. If the flaps are made of adequate size, the opening of the left pleural cavity will provide a sufficiently large approach for the required decortication of the inferior and posterior surfaces of the heart.

Symptomatology of Panmyelophthisis—Weindel and Engel say that Frank's description of the symptomatology of panmyelophthisis stressed three essential symptoms: (1) grave anemia, (2) inflammations with the anatomic aspects of diphtheria, which are followed by sepsis, and (3) morbus maculosus haemorrhagicus. The authors describe the histories of several patients observed in their clinic. On the whole the cases correspond in their symptomatology with that given by Frank. The first and third points stressed by Frank were always demonstrable but the diphtheric inflammations were not quite as regular. The blood pictures always showed a reduction of the morphologic constituents of the blood. Erythrocytes, leukocytes and thrombocytes were always equally involved. However, in the beginning stage of the disease one of the morphologic constituents may be destroyed more rapidly than the others, so that another form of blood disease may be thought of. In the differential blood picture there are great differences. As a rule, however, the cell forms are normal and only their reduced number indicates the nature of the disorder. In some instances the young forms are relatively increased, while in other cases the cells with vital granulations are increased as indication of a reduced regenerative capacity. The exact status of the bone marrow can be detected only in the course of the necropsy. In addition to the true form of panmyelophthisis there are a number of other blood diseases in which only a part of the bone marrow is destroyed. Among these there are two definite forms: the agranulocytosis of Schultz and the morbus maculosus of Werlhof. The first of these cannot always be differentiated from panmyelophthisis, but the course of the second is nearly always differentiable. Occasionally some forms of blood diseases apparently develop into a panmyelophthisis. In all lesions of the bone marrow, toxins seem to be the eliciting cause. The authors believe that different chemical and bacterial toxins, if they are present in sufficient quantities and for a sufficient time, produce one of the blood diseases and impairment of the bone marrow. Attempts have been made to bring the various lesions of the bone marrow into a nosologic system. The authors consider the best one that suggested by Naegeli, who differentiated (1) aplastic anemia, (2) agranulocytosis, (3) thrombopenia, (4) aleukia (the combined symptomatology of 2 and 3) and (5) panmyelophthisis (a combination of the symptoms of the first three). The treatment is chiefly symptomatic and consists primarily in blood transfusions.

Rupture of Uterus Following Cesarean Section Case G Steigelmann—p 1524
Fluorine as Specific for Parathyroids M Callam—p 1534

Operative Treatment of Varicose Veins—Romich thinks that the failures in the treatment of varicose veins are partly due to the fact that the difference between varices and strong veins is frequently not given sufficient consideration and that occasionally strong, healthy veins are ligated. After discussing the pathogenesis of varices, he shows which parts should be ligated and which should not. He demonstrates that the intervention is considerably simplified by making percutaneous ligatures and by subcutaneous severing of the veins. The advantage of this procedure is that no cutaneous scar is produced and no ligatures remain in the skin. Moreover, it makes possible the ambulatory use of the operative treatment. The author deplors that the percutaneous ligature, which Kocher used in operations on veins, has been given up, for it is suitable also in connection with the injection treatment.

Fluorine for Parathyroid Insufficiency—Callam points out that fluorine can be used with good results in disorders in which there is insufficiency of the parathyroids. He prescribes a 1 per cent solution of chemically pure sodium fluoride in distilled water, of which the patient takes from five to eight drops in a teaspoonful of water four times daily. He asserts that, if the sodium fluoride is given in these quantities, there are no toxic effects. An indication of the efficacy of sodium fluoride is the disappearance of the cicatricial keloids after from two to three months of medication. Callous scars decrease in size and become so soft that they hardly differ from the surrounding skin. This applies to external scars and is true also of urethral, vaginal, esophageal or other scars. The author thinks that, aside from surgical stimulation of the parathyroids, the medication with sodium fluoride is the best treatment for scars. That sodium fluoride has connections with the parathyroids is indicated by the author's observation that, in the dosage mentioned, sodium fluoride is a good antispasmodic in infantile eclampsia and in epilepsy of children. Moreover, sodium fluoride is helpful in suppurations and inflammations of the bones, in exostoses and in fractures that fail to heal. The author thinks that it might likewise be tried in bone sarcoma. He suggests investigations on the effect of fluorine on the calcium content of the blood, osteomalacia, osteitis fibrosa and experimental tetany following removal of the parathyroids.

Clinical Significance of Determination of Concentration of Organic Substances in Cavity Fluids. I Schulutko—p 1161
Peritonitis in Scarlet Fever N Vučetić—p 1163

Determination of Organic Substances in Cavity Fluids—Schulutko points out that the determination of the concentration of organic substances in fluids makes it possible to differentiate exudates from transudates. The Rivalta reaction is often used for this purpose. Another method is that suggested by Castellino, but this test does not indicate the concentration of a fluid and, according to Kartaschowa it has only slight clinical value. The author employed the method of Model, which is based on the observation that organic substances become oxidized by a chromium mixture. To 0.5 cc. of the fluid to be examined is added 15 cc. of a decinormal solution of potassium bichromate and 30 cc. of concentrated sulphuric acid. This mixture is left to cool, is diluted with distilled water to make 100 cc. and is again left to cool. Then 5 cc. of a 10 per cent solution of potassium iodide is added and the precipitated iodine is titrated in the presence of starch by means of a decinormal sodium thiosulphate solution. The quantity of sodium thiosulphate required for the titration is subtracted from the quantity of the decinormal solution of potassium bichromate that was added in the beginning and is multiplied

by two (for computation for 1 cc. of the fluid to be examined). The number thus obtained is called the reduction index and indicates the sum of the organic substances, that is, the higher the reduction index, the greater the concentration of organic substances. The author used this method for the examination of transudates and exudates, but particularly for the determination of the concentration of organic substances in the bile. He points out that under normal conditions the concentration of the B bile is greater than that of the A and C biles. Further he shows that under pathologic conditions (hepatitis, angiocholitis, cholecystitis, cholelithiasis and so on) the concentration of the bile increases. He gives tabular reports of the concentration of organic substances in the bile (A, B, C), which he determined by means of Model's method in the various disturbances, those without and those with involvement of the biliary system. In patients with symptoms of cholecystitis, he found that the reduction index was from two to three times as high as in persons without these disturbances.

Regulation of Growth Equilibrium of Epithelium and Connective Tissue by Factors That Increase Cell Permeability and Their Significance for Cancer Problem Traube and Else Knake—p 324

Copper Content of Jensen Sarcoma—Edlbacher and Gerlach explain the connection of their studies with former investigations. In this report they consider the problem of whether the copper and iron content of experimental tumors shows peculiarities. On the one hand, they studied the various parts of tumors for their copper and iron content and, on the other hand, they investigated whether there are relations to the copper metabolism in other portions of the animal organism, particularly the liver. The experiments were made on white rats. These animals had been subcutaneously inoculated with Jensen's rat sarcoma. In the first series of animals the authors determined the copper-iron content of the tumor and of its necrotic part and the copper content of the liver, spleen and kidney. In the second series, neoplasms of various ages were examined for the copper and iron content of the tumor and of its necrotic part. In the third series the problem was whether the copper metabolism could be influenced by intensive copper storage of the organism. The authors found that the average normal copper content of the liver per gram of moist substance is 3.2 microgram but that it fluctuates between 1 and 6 micrograms. The spleen has a considerably lower copper content, namely, 0.3 micrograms, while the kidney has a relatively high one of 3.4 micrograms. The copper content of the liver is apparently subject to fluctuations, tumor animals showing low as well as high values. It was found also that within the tumors the copper content varies greatly, there being considerable differences between the necrotic center and the rapidly growing periphery of the tumor. The necrotic portion always contains considerably larger quantities of copper than the growing tumor tissues. This difference is always present and is apparently independent of the absolute copper content, the quotient of the copper content between the necrotic portion and the tumor being always the same. The authors point out that in this respect their observations corroborate those of another investigator, who also observed a higher copper content in the necrotic portions than in the surrounding tumor in the Ehrlich-Putnoky rat tumor. They think that in view of the rapid growth of the tumors it is reasonable to assume that the copper in these inoculation tumors comes from the organism of the host. They found that while the quotient between the necrosis and tumor remains the same, the absolute copper content of tumors decreases with the course of time. In this respect the authors' observations differ from those of another investigator, who observed a continuous increase. In their studies on the effects of copper storage, the authors observed an inhibition of the tumor growth following the introduction of copper. They think that the question of whether the copper content of malignant tissues and their necroses exerts an influence on the

increased enzymatic action of these tissues must be answered in the negative. However, they consider it possible that the increased copper content of the necrotic tissues might be related to the enzymatic changes that take place during necrotization.

Carcinoma Reaction with Aid of Bacterium Coli—Cizek states that in an endeavor to simplify the Fuchs cancer reaction he utilized for the demonstration of proteolysis of the fibrin substrates the capacity of *Bacterium coli* to form indole from the cleavage products of protein, which contain the tryptophan group. In this case indole can readily be demonstrated by the Ehrlich test. This cancer reaction is simple and, on the basis of the author's observations, comparatively reliable and specific. Of thirty untreated cancer patients, twenty-seven (90 per cent) had a correct reaction, two (67 per cent) an incorrect reaction and one an indefinite reaction. In seventy-nine control cases the results were correct in seventy-four cases, incorrect in two cases and indefinite in three cases.

- Experiences with Evipan Anesthesia H. Geiger—p. 2243

Hypertension and Denervation of Kidneys—Uebelhor points out that the suggestion for the separation of the kidney from its sympathetic nervous system for the purpose of reducing the blood pressure came from animal experiments in which it was observed that the denervated kidney is protected against various injuries, owing to the elimination of vascular spasms and the better blood perfusion. Since complete denervation seemed to accomplish more than simple decapsulation, it was suggested that denervation be resorted to in certain cases of glomerular nephritis and particularly in not fully developed nephrosclerosis. The problem of blood pressure was studied by several investigators, who reasoned that denervation counteracts an injurious spasm of the renal arterioles. The author cites several surgeons who resorted to renal denervation and reported some favorable results, but in some cases the reduction in blood pressure disappeared again after a few weeks and after that the disorder took its usual course. The author observed two cases in which the treatment was a complete failure. He stresses that the object of this report is to call attention to the fact that renal denervation and operations on other organs produce similar results as far as the blood pressure is concerned. The considerable decrease in a fixed hypertension and the improvement in some subjective symptoms persists not only for a few days but for months. The author has no explanation for this observation, the less so since the hypertension did not have the same cause in the patients in whom these improvements were noted. The postoperative reduction in blood pressure was observed in the majority of patients with hypertension, but in some it lasted only for a short and in others for a long period. The reduction lasting for only a short time may be explained by the operative shock and by the effect of the anesthesia, however, a reduction of several months' duration cannot be explained in this manner. To be sure, operations are often followed by an improvement in the general condition that cannot be wholly explained by the removal of a diseased organ. The author emphasizes that he does not wish to discourage further attempts to improve hypertension or preuremic conditions, but he points out that renal denervation can be justified only if it accomplishes more than some other operation or the internal treatment.

Dupuytren's Contraction.—Niederland points out that although the anatomic aspects of Dupuytren's contraction are well known its etiology is still disputed. He is of the opinion that (1) in rare cases a single trauma may produce a Dupuytren's contraction, (2) in some cases hereditary factors without a demonstrable trauma may be the cause, (3) in the majority of cases it is the result of chronically recurring traumas of the inner surface of the hand, such as repeated mechanical injuries from tearing, pressure or jerk, and (4) careful attention to all factors, particularly to the occupational aspects, will reveal that it is an occupational disorder in the majority

of cases. He reviews and attempts to disprove the objections that have been made against points 3 and 4 and concedes that as yet it is an open question whether traumatic influences are as such capable of producing Dupuytren's contraction or whether they can do this only on the basis of a hereditary predisposition. He points out that whether this question will be answered in the affirmative or the negative will have no essential effect on the estimation of the disorder as an occupational disease.

- Röntgenologic Control of Madlener's Method of Sterilization J. Russa—p. 2188

Danger of Intra-Uterine Pessaries—Gesenius gives a history of the use of intra-uterine pessaries. He cites some of the bold claims that have been made for the use of some intra-uterine pessaries. A review of the literature reveals several hundred cases of severe complications and forty-one fatalities caused by the most common forms of pessaries. These figures do not include the uncomplicated abortions, and the incidence of severe complications and fatalities is doubtless much higher, since only a small portion of such cases are reported in the literature. If conception takes place while the woman wears a pessary, septic abortion may result. Sterility or tubal pregnancies have been known to result after the use of pessaries. Moreover, stem pessaries have been known to perforate into the abdominal cavity, the rectum or the bladder. Some authors believe that certain types of pessaries may cause deformities of the fetus. He describes a case in which the forensic aspects of the introduction of pessaries came up. He thinks that the time has come when the medical profession should assume the stand that the introduction of foreign bodies into the uterus is an "act of negligence." This attitude has been adopted by the Berlin medical society.

Appendectomy as Etiologic Factor in Biliary Disease?—Schubert directs attention to a report by Scharf in which that author states that he observed a high incidence of biliary diseases following appendectomy and that two other authors had made similar observations. In accordance with this, Scharf has recommended (1) inspection of the gallbladder during every appendectomy and (2) removal of the appendix only when absolutely necessary, never for prophylactic reasons. Schubert, however, objects to Scharf's stand. He analyzes his own material of several hundred gynecologic laparotomies in the course of which he removed the appendix, whether it was diseased or normal, not only because he himself had frequently observed the development of appendicitis shortly after a gynecologic laparotomy but also because other leading surgeons had advised prophylactic appendectomies in connection with every laparotomy. In studying the postoperative records of his patients he finds 117 per cent of postoperative biliary disorders. He thinks that, in view of the rather high incidence of biliary disease, the same number might be expected had the appendix not been removed. In this connection he cites Truesdell, who in the course of several hundred laparotomies in women observed that almost 10 per cent had gallstones. Moreover, in gynecologic operations in which the appendix was not removed the postoperative incidence of biliary disease was 145 per cent, that is, it was higher than in the operations in which the appendix had been removed (117 per cent). On the basis of these observations he rejects the assumption of connections between a prophylactic removal of the appendix and postoperative biliary disease, because it lacks corroborative evidence.

HYSTERICAL PARALYSIS AND ITS TREATMENT

ABRAHAM MYERSON, M.D.
BOSTON

Hysteria, like many another concept of medicine, is a fusion of conditions that resemble but are not identical with one another. From the hysterical state that is a total alteration of personality to the case in which hysterical manifestations appear as a sort of foreign body in the personality is a wide gap, which extends from an innate or constitutional disorder to an easily curable condition.

The group of cases here presented have a physiology or, at any rate, a physiologic psychology which, once understood, opens the doors to a rapid cure. But unless their mechanism of disability is understood the patients may be markedly incapacitated and wander from physician to physician vainly seeking help. In other words, a superficial pathologic condition blocks the normal conduct reactions of the individual as thoroughly as the deeper lying disorder in those cases in which hysteria is really a psychosis demoralizes the individual.

The first cases of this group make up a sample wherein there is disturbance in the flow of muscular power which constitutes the so-called hysterical paralysis. Something occurs, either accident, injury or disturbing emotional state, by which a part becomes immobilized for a time. In its genesis the paralysis represents what I here call the hysterical amnesia for the proper interaction of muscles to produce motion. More simply, there is a sort of forgetting of the mechanism of successful motion and a substituted disorder, which produces paralysis.

REPORT OF CASES

CASE 1—K. W., a man, aged 22, single, a salesman, whose early history was entirely negative for neurotic or hysterical manifestations, was playing football eight weeks before being seen and was knocked unconscious for one and one-half hours and was hazy the next day. In the hospital to which he was taken, it was stated that there was a fracture of the first lumbar vertebra. He stated that both legs felt paralyzed and anesthetic at first. The anesthesia of both legs remained for some time, then that of the left entirely disappeared and the right improved but had remained more or less anesthetic ever since. He was unable to use the right leg although the left leg had entirely recovered. The right leg was "numb" as well.

Physical examination was entirely negative except for the right leg. The knee jerks on both sides were lively and equal. Ankle jerks were lively and equal. There was no Babinski reflex. There was almost complete anesthesia below the right knee. The anesthesia ran circularwise around the leg in typical hysterical fashion. As he attempted to lift the leg, the muscles on both sides of the thigh contracted violently, that is the quadriceps contracted vigorously as did the flexors. The toes were moved but slightly. The wrong flow of power was distinctly evident, that is to say when the attempt was made to

raise the leg from the table, the agonist and antagonist were contracted. This set up a deadlock between the two groups of muscles and, naturally, motion became impossible.

The immediate psychogenesis of the situation seems simple enough. There was undoubtedly some cord injury at first, which set up a numbness of the legs and weakness. This disappeared but left behind it a state of fear and one of amnesia for the proper use of the muscles of the legs. This condition was explained to the patient. He was told that he would be able to walk when he left the office. A powerful electric current was given to the muscles of the front of the leg. They contracted vigorously. This continued for a few minutes. The patient was told to watch the muscles contract, and it was stated to him that he must try to help the electric current and contract the muscles with each stimulation. In a short time the current was discontinued surreptitiously, and the patient continued to move his leg with no electrical stimulation. Shortly thereafter he was able to move his leg perfectly well and walked out of the office with no drag whatever to his leg.

CASE 2—K. B., a housewife, aged 44, was one of a group of patients in whom "medicolegal trauma" operated as the initiation of a hysteria. The usual claim that in a case in which litigation is proceeding a cure cannot be effected while the litigation is going on is upset by this case. Three years before, the patient was in an accident and suffered severe injury to the leg, especially around the patella. The leg was painful and stiff, there was an injury to the cartilage. A year afterward a cartilage was removed from the left knee. Since that time the leg had been held rigid and there had been no power of extension or flexion at the knee. She had walked about, dragging this leg. The question of operation had now come up, since the situation had not improved, despite physical therapy of an extensive and persistent type. At the time of the accident the patient injured the left arm, but this member had almost completely recovered, although there was some numbness and tingling. The patient struck her head at the time of the accident and had headaches and dizziness even at the time of examination. However, the main complaint concerned the left leg.

The patient walked without extending or flexing the left knee, and there was little motion at the left hip. However, there was very little atrophy of the left thigh. Both knee jerks were equal, although the left required reinforcement for its appearance. When reinforcement was used, it was equal to that of the right side. When the leg was held up and the thigh supported, the knee dropped. However it was noticed that when this happened the hamstrings contracted and assisted gravity in pulling the leg down. There was absolutely no power to extend the leg voluntarily at the knee. There was some power to extend the leg at the hip, that is when the entire leg was supported and the patient was urged to do so, she could flex the thigh on the abdomen. There was no general loss of sensation, although there was an absence of tickle reaction on the sole of the left foot. Further examination showed that, when the effort was made to extend the leg, the hamstrings contracted while the quadriceps did not. On this basis, namely, that the antagonists were called into play rather than the agonists a diagnosis of hysteria was made and the patient was advised as to the situation, reassured that the condition was entirely curable, and the rather bold statement was made that she would not be allowed to go home until she used the left leg as well as the right.

The electric current was tried but had no value in this case. Although the muscles contracted vigorously with the galvanic

current and she experienced definite pain, she was still unable to use the leg voluntarily. Another technic, therefore, was used, based on the following observation. Ordinarily, when the leg is flexed at the hip on the abdomen, the quadriceps is thrown into associated activity in an involuntary but synergic fashion. Therefore, the patient was instructed to flex the hip vigorously. After a while she did this, and it was then noted that the quadriceps contracted and the leg, when the support of the physician's hand was removed, did not drop immediately or rapidly to the table. The patient's attention was called to this, and she saw for the first time that there was power in the quadriceps of the leg. The flexion of the hip was repeated fifteen or twenty times, after which the quadriceps was contracting vigorously. She was then able to hold the leg off the table. With the continuance of this exercise, the patient's will obtained control of the quadriceps muscle and in half an hour after the treatment was commenced she was using the leg as well as ever and performed all the motions without the flow of the effort into the hamstrings but properly into the muscles normally utilized for the motion.

It is noteworthy that when the power first returned to the quadriceps there was a marked coarse tremor of that muscle. This disappeared, and the patient has remained well since.

CASE 3—A youth, aged 16 years, a strong and powerfully built boy, twisted his back, Sept 19 1934, while playing football. He had pain at this time but felt well continuing to play football until September 25, when he had severe pain in the front of the body near the pelvis and running up the abdomen. He quit playing football. The pain was so severe that he took to bed and had remained there ever since. At first he had a temperature of 101 F, with rigidity of the abdominal muscles. The bowels were constipated. The temperature dropped in a day or two, and a roentgenogram at the hospital showed a separation of the symphysis. Since that time he had been in bed except to go to the bathroom, and this he did with much assistance and much dragging and scuffling of the feet.

He was examined by a surgeon, who found no orthopedic abnormality and who referred him for neurologic study. He was a large boy and was supported by others when he walked. He dragged both legs. There was very slight flexion of the thigh on the hip, slight extension of the leg on the thigh, and foot drop on both sides. The cranial nerves and the arms were entirely intact. Thorough examination of the legs revealed no organic neurologic signs. When he attempted to move the legs, the muscles were thrown into a coarse tremor. The muscular exertion seemed powerful, but it was obvious that the agonist and the antagonist were being contracted at the same time. There were no sensory disturbances of any type.

It was explained to him that his entire condition was due to fear that he would be able to walk if he put himself into a calm frame of mind regarding his condition, and that the separation of the symphysis, of which he had been informed was of no practical consequence. Rapid passive motions were made, and he was asked to cooperate as best he could. After a dozen or more such passive motions had been made the leg was suddenly released, and it was found that he was using his leg with force and precision. From motions while on his back, instruction was continued while the patient was on his feet. There was a remarkably quick transition from helplessness to perfect control of motions of the legs, so that he walked out of the office without any difficulty whatever.

In this particular case the mechanism seems to have been first pain, then fear, and as a resultant of the psychologic situation a physiologically wrong innervation of the muscles of the legs. The correction was a simple matter of encouragement, instruction and some trickery (I have labeled this trickery "legitimate hocus-pocus").

CASE 4—A housewife, aged 35, also demonstrates that traumatic hysteria may be genuine and that the patient suffering from such a condition may make an honest effort to get well. The patient was seen Dec. 5, 1934. A year before she was in an automobile accident. The car in which she was riding tipped over and all the passengers fell out in a heap. She was not rendered unconscious but was shaken, bruised and cut. She was out of bed in two days but noticed that the right arm commenced to shake. This continued, grew worse, and reached the stage at which she could not use the hand for writing or

for any of the ordinary purposes, so that she has been compelled to do most of her work with the left hand. Shortly afterward it was noticed that there was side-to-side, rotatory shaking of the head. There was no pain. Her sleep was poor, she tired easily. At times she became generally shaky.

She was sturdy and well developed. There was at times a rotatory lateral tremor of the neck and head. This often disappeared but generally was quite conspicuous. The right arm, when extended, showed marked tremor, and this was quite extreme in the finger-to-nose test. The left arm showed a very slight tremor. Reflexes of the arms were equal and active. There was no apparent tremor of the right leg. Motions of the legs were intact. Reflexes of the legs were somewhat hyperactive and equal. There were no pathologic toe signs. There was a very marked midline right-sided diminution of sensation throughout, including the face, palate, right eye, right nostril, mucous membrane of the mouth and the right side of the chest and abdomen, including one half of the vagina and the entire right leg. The abdominal reflexes were normal. The visual field that concerned the right eye was diminished throughout, that which concerned the left eye was normal. It was also noted that the tremor of the arm depended on the overuse of the muscles concerned with motion. Any one can create a tremor of his arm who will overcontract the muscles of action, especially if he contracts the antagonists at the same time. There was some doubt as to whether this was not a case of multiple sclerosis, but the general alignment of symptoms and signs finally indicated that it was hysteria.

The treatment here was first to change the anesthesia of the right side into normality by the use of the strong galvanic current, after the use of this current on a few occasions, the anesthesia disappeared. With relaxation exercises, together with the judicious use of stramonium, the tremor disappeared, and six months later there was only a slight amount present.

There is no satisfactory explanation of the fact that half of the body disappears from consciousness so far as skin sensation is concerned. There is, of course, a numbness of the hands or any part of the body experienced under violent emotion and it may safely be said that in the mechanism of emotional injury is the superficial explanation of hysterical anesthesia. The electric current was used merely to "recall" the part into consciousness. This it succeeded in doing. The tremor was obviously due to the wrong use of muscles. When this was corrected, the tremor disappeared.

The next two cases concern situations that were so deeply rooted in the entire attitude of the patients that any ordinary approach, as involved in suggestion, explanation or the use of electric currents, was unavailing. Consequently, a more radical attack was instituted.

CASE 5—G K, a young man working as a laborer, felt a sharp pain in his back while doing some heavy work lifting. It happened that he was working for himself and, consequently, there was no medicolegal situation involved and therefore no "compensation neurosis." However, the pain increased to the point at which he became entirely incapacitated, and his back assumed a marked flexed position and the body was rotated somewhat to the left. He was in one of the important hospitals of Boston for about six weeks. Roentgenologic studies were instituted with the result that nothing organic was found, after which interest in him lapsed. A few efforts were made psychotherapeutically to encourage him to get up, with no results of importance. He was taken home and had been in bed some three months entirely helpless when he was seen.

He was a stalwart young man and lay in bed, more or less curled up, the legs flexed on the abdomen, the back held rigid by contracture of the long muscles, which stood out like whipcords and which could not be relaxed by persuasion, pleading or suggestion. It was then explained to him that he was holding his back rigid more through pain and fear than through any organic situation. It was suggested that he take some ether, he was told that the muscles would be relaxed under ether, that when he 'came to' he would be walking without trouble and without pain. His wife was instructed to assure

him that this would be the result until the therapeutic anesthesia was to be given the next day. At the time appointed he was anesthetized to the state just beyond primary ether. The muscles were entirely relaxed, the back became entirely straight. An assistant put him on his feet and held him in an erect position. He was then marched to and fro by the assistant and the patient's wife. At the same time I spoke to him encouragingly, telling him that the pain was gone and that he was able to walk. As the ether wore off and consciousness returned, he found himself walking to and fro in an erect posture. As consciousness became clear, he discovered to his surprise that his back was free and flexible and that he was able to bend and to walk in a normal fashion.

The patient was seen three years later. At this time he had pain in his back as a result of his work. This pain was declared by a competent orthopedic surgeon to be due to a sacro iliac condition, for which he continued to have treatment for a long time. There was, however, no distortion of the back and no hysteria at this time.

CASE 6—W H, a man, aged 43, single, of high scholastic attainments and a professor in a great university presented perhaps the most interesting case of this series. The personality of this man is one that markedly deviates from the ordinary. He had a boyhood and youth of extreme struggle and great devotion to learning, a devotion that led through the garret type of existence to a chair in a university. He is a solitary man, entirely celibate, but undoubtedly his inner life is not so placid as his actions would lead one to believe.

About fifteen years ago he had a neurosis which was associated with difficulty in swallowing. This difficulty never reached an extreme grade and after an extended rest he recovered, at least outwardly. His career continued and from time to time he had slight recurrences, which ran the following general course. There was first a loss of appetite with general anxiety, sleeplessness and fatigue. There developed fear of choking which, to some extent, was traceable to his excursions into psychiatric literature, then there appeared an inability to pass the food beyond the mouth and finally the disappearance of the ability to swallow solid food and a marked difficulty in the swallowing of liquids.

When he was seen, July 10, 1931 he had already been sick some six weeks. The attack was the worst he ever had. He had lost weight although the anxiety had disappeared and he was sleeping fairly well, but the difficulty in swallowing had become quite central in the symptomatology and had reached the point at which a crisis had developed. "In swallowing he puts the food in his mouth, the tongue then gets in the way, he puts his head forward gulps strains, chokes and in a considerable period of time manages to swallow part of a mouthful. By dint of considerable application and concentration he manages to do away with two or three glasses of milk a day at the expense of a large part of his time."

He was unable to receive treatment from the neurologist who cured him in his first major neurosis. He visited a psychoanalyst, who told him that it would take a long time to be psychoanalyzed and consequently he had better seek some other type of treatment because of the nutritional emergency. He was sent to a hospital. An effort was made to increase his appetite by bitter tonics and by exercise, but no real or substantial change took place. It was then decided that if the fear of swallowing could be displaced for a short time so that automatic swallowing could take place he would recover.

The only approach to this end seemed to be through anesthesia. There were two treatments given. Prior to the first he was informed that on the following day he would be given anesthesia in a mild form, that when he recovered consciousness, he would be able to swallow liquids without any trouble whatever. The next day he was given nitrous oxide. As he became unconscious, a glass of milk was put to his mouth. As he started to recover consciousness he was instructed in peremptory fashion to drink. He did this, drinking quite freely and by the time he recovered complete consciousness he found himself drinking with freedom and without any difficulty whatever. He continued to drink without any trouble thereafter. Three days later the experiment was repeated except that he was assured that he would find himself eating solid food. By this time he was quite prepared to believe that this

would be the case. When the mask was removed, a sandwich was handed to him. He was enjoined to eat it and the meal was finished by the adjournment of the physician, the assistant and the patient to a restaurant where all three had a hearty meal, the patient eating with as much dexterity as the others.

In the four years that has elapsed the man has continued to be well. There has been no recurrence of the difficulty. Whatever deep and dynamic complexes are at work in his subconsciousness, they have not interfered with his success, and whatever role they may have played in the difficulty of eating and drinking has also disappeared back into the unconscious.

Superficial as the treatment may have been, results were excellent. Moreover, this man is not the type who would yield himself to a psychoanalysis or any other intimate form of self revelation. His whole instinct is to hide his intimate feelings from the scrutiny of others. His solitariness is, in large measure, conditioned by this phase of his psychologic make-up. He continues to be a valuable member of society despite his shut-in personality. Probably it is better for scholarship and culture that he continues to manifest this peculiarity, since his singular excellence is probably dependent on his escape from the distractions of society.

COMMENT

These cases are undoubtedly of the kind that make up the roster of miracles, by which healers, saints and shrines build up their reputation. They are here recorded to show that the pathologic condition disappears when the symptoms are explained physiologically and the therapeutics is rationally directed.

THE HEMOLYTOPOIETIC EQUILIBRIUM AND EMERGENCY SPLENECTOMY

CHARLES A. DOAN, M.D.

GEORGE M. CURTIS, M.D.

AND

B. K. WISEMAN, M.D.

COLUMBUS, OHIO

Despite the mystery that has surrounded the spleen in the past, and the ignorance that still persists with reference to the exact nature and variety of its physiologic functions, two important activities are now definitely established as centering in this organ: one, the reservoir capacity for red and white blood cells,¹ the other, the phagocytic, destructive activity of the reticulo-endothelial elements, the clasmotocytes of the splenic pulp, for old or injured erythrocytes,² granulocytes,³ and blood platelets.⁴ Under physiologic conditions

there is maintained in health a nice balance between bone marrow hematopoiesis and these splenic functions of cell storage and cell death. To express succinctly this reciprocal relationship between the organs subserving these antithetical functions, Krumbhaar⁴ proposed in 1923 the term "hemolytopoietic equilibrium."

It has been the experience in medicine that, whenever any physiologic function is recognized for any organ, a disease entity due to a corresponding pathologic dys-

of spontaneous or of precipitated origin, and irrespective of the severity of the anemia that may develop.

During the past five years our clinical investigation of diseases involving the spleen has resulted in advising and in consummating splenectomy in thirty-one cases. In each instance careful and thorough laboratory studies were made the basis for differential diagnosis and for an attempted appraisal of the hemolytopoietic equilibrium, preliminary to, during, and subsequent to removal of the spleen. Seventeen of the cases represented a variety of syndromes—thrombopenic purpura, Banti's disease, hypoplastic anemia, leukanemia (persistent extreme splenomegaly after two and one half years of medical treatment), chronic myeloid and lymphoid leukemia (with intestinal obstruction from splenic tumor), and polycythemia vera (with cirrhosis and repeated hemorrhages from esophageal varices). The details of these cases will be presented elsewhere. The indications for removal of the spleen in each individual in this group we believe to have been valid, but in some instances, as parenthetically suggested, the cure of the principal underlying disease was not the basis for operating. The operative mortality in this group was five, three of the fatalities being far advanced cases of Banti's syndrome, two patients with early Banti's disease survived splenectomy and have been greatly benefited by the procedure up to the present writing. The technical difficulties of splenectomy in advanced Banti's disease suggest reliance on ligation of the splenic artery as the procedure of choice if operative intervention is necessary.

Chart 1—Postsplenectomy cellular reactions in fourteen cases of congenital hemolytic jaundice.

function may be anticipated and sooner or later will be encountered. Specific clinical entities each involving a disturbance in one or more of the functions just mentioned for the spleen are known. In congenital hemolytic jaundice we recognize a simple dominant familial tendency for the erythroclastic functions of the spleen to become overemphasized to the point of clinical signs and symptoms. In certain types of purpura the thrombopenia may be of splenic origin. The leukopenia of Banti's and of Felty's syndromes is associated with splenomegaly. In each of these several pathologic states the surgical removal of the spleen in the more chronic stages of activity has resulted in clinical improvement coincident with the correction of the specific cytologic deficiencies involved.

Experience with splenectomy in the past, however, has led to the almost universal dictum that operative intervention is distinctly contraindicated in the presence of an acute splenic crisis⁵. It is our belief, on the contrary, that if the pathologic physiology of the spleen is adequately understood, and its relationship to the hemolytopoietic equilibrium recognized, splenectomy—emergency splenectomy if you please—is not only indicated in the more acute exacerbations but demanded as a life saving measure, whether the hemoclastic crisis is

Fourteen splenectomies were performed with no operative deaths in patients with a readily established diagnosis of congenital hemolytic jaundice. In this second group, removal of the spleen was accomplished in four patients during a quiescent interlude of the disease as a prophylactic procedure, in five patients, operative intervention was decided on during a subacute

exacerbation of the hemolytic process, and in five critically ill patients the spleen was removed as an emergency procedure with the total red count rapidly approaching or actually under 1,000,000 cells per cubic millimeter in a fulminant, acute, hemoclastic crisis. While the evidence on which our decision to advise operation during the acute stage of an erythroclastic crisis was obtained from a careful study of the changes induced immediately following splenectomy in the more

chronic phases of the disease⁶ (chart 1), we shall limit this discussion to the results of emergency splenectomy the more sharply to emphasize the spectacular hematologic and clinical recoveries (chart 2) that at times follow speedily on the removal of this organ, and at the same time to point out the grave dangers to life which exist when the spleen begins to exert an excessive destructive action on any of the circulating elements of the blood and/or an undue inhibitory effect on bone marrow hematopoiesis.

Much discussion continues to center about the relative roles of spleen and bone marrow in certain hemato-cytopenic states. In those deficiency states of the blood entirely unrelated to the spleen, the removal of this organ is not only useless but definitely contraindicated. The most meticulous differentiation of underlying mechanism in each case must therefore precede the outlining of any rationale of therapy. Our emergency splenectomies, i. e., those performed with the total red count near the 1,000,000 level, have been limited to patients with congenital hemolytic jaundice, to selected instances of thrombopenic purpura, and to certain cases of hypoplastic anemia. In the first condition we believe that the spleen is the primary seat of the pathologic condition, in the latter two, the splenic influence may represent an important factor in the existing cellular disequilibrium.

HEMOLYTIC JAUNDICE

The sensitiveness and lability of the "zonal" cellular variations from moment to moment, as revealed in carefully controlled, frequently repeated, counts of the peripheral blood elements, were established some years ago⁸ and have been repeatedly confirmed. As a consequence, in our first studies of clinical cases of chronic congenital hemolytic jaundice⁶ daily estimations of the various cell levels were made for periods of three months or longer to establish thoroughly the range of fluctuation existing before operative intervention was undertaken. Then on the day of operation blood studies were made at fifteen minute to half hourly intervals throughout the day, with the astonishing discovery that instead of the erythrocyte increase, as described in the literature, coming in from one to three months following the removal of the spleen, a major increase, frequently of 1,000,000 or more red blood cells per cubic millimeter, occurred immediately—before the patient left the operating table, irrespective of the preoperative level of the total red cells. This phenomenon was observed not occasionally or sporadically but regularly, whenever sufficient hematologic studies were made (chart 1). Hemoglobin, hematocrit, leukocytes and thrombocytes likewise rose promptly in sufficient magnitude, coincident with a dramatic clinical improvement, to suggest strongly an absolute increase in available circulating elements rather than a concentration phenomenon of the plasma only. A progressive decrease in icterus index and reticulocytes, which always follows removal of the spleen in hemolytic jaundice, reflected the elimination or subsidence of the hemolytic process. Moreover, the gradual return of the red cells to a more nearly normal diameter and volume and the increase

to a more nearly normal range of their resistance to hypotonic saline solution seemed to be evidence of the increased efficiency of the bone marrow in the absence of splenic influence. In short, the data obtained suggested that the epinephrine stimulated and manipulatively induced disgorgement of the sequestered blood cells from the splenic reservoir incident to operation, and the sudden elimination of the destructive activity of the splenic phagocytes renders more effective the unusually active erythrocyte delivery and erythropoiesis that characterize the bone marrow in hemolytic anemia. Subsequent blood volume studies have established beyond question the validity of these first assumptions.

The gradual accumulation of such facts as have been cited formed the background for a growing conviction that, given proper medical judgment and adequate surgical management, the patient in acute erythroclastic crisis should respond even more dramatically and promptly to the surgical removal of the spleen than those patients seen in the subacute and chronic phases. The first test of this hypothesis came in a little girl.

CASE 1 (chart 2)—G. P., a girl, aged 4 years, during the month of August 1933 became gradually less active, fatigued easily, grew pale, then slightly icteric, and when finally seen by her physician had only 869,000 red blood cells per cubic millimeter. Despite intensive liver therapy, at the end of ten days the red count was only 600,000, the jaundice had increased, the spleen had become palpable, the peripheral lymph nodes were shotlike, and, a high leukocyte count being recorded, the diagnosis of acute lymphatic leukemia was made. In consultation, however, on careful laboratory study, we found the apparent elevation of the leukocyte count to represent for the most part nucleated red blood cells with little qualitative or quantitative deviation of the leukocytic formula from the normal. Approximately 100 per cent of the red blood cells were found to be reticulated, and a macrocytosis rather than the usual microcytosis existed in this child. The mother and the maternal grandfather, who were examined at once, both showed the laboratory stigmas of congenital hemolytic jaundice. The child was moribund. It was decided to give a small transfusion, since the jaundice was slight, indicative of liver efficiency in handling satisfactorily the increased pigment, and the renal function was apparently good. Following 200 cc of the father's matched blood a temporary rise in the total red count to 900,000 occurred, however, within twelve hours the count again totaled only 660,000 and the hemoglobin 2 Gm per hundred cubic centimeters. A second transfusion of 200 cc. from the original donor raised the count to 1,190,000, but twelve hours later the erythrocyte count was 810,000, the jaundice had perceptibly deepened, the spleen had definitely increased in size, the temperature was 101.8 F, pulse 120, respirations 30, systolic blood pressure 75, diastolic unobtainable. It was perfectly obvious that more transfusions were contraindicated, liver therapy had already been given a ten day trial by the first attending physician. The only possible hope lay in splenectomy, if the child could survive the ordeal. The courageous parents accepted this decision after a full explanation of the facts, and an emergency operation was performed at midnight by Dr. Verne Dodd, surgeon-in-chief, at the University Hospital, under nitrous oxide-oxygen ether anesthesia. The spleen as removed weighed 212 Gm. Immediately prior to operation, at 11 p. m., the patient had a temperature of 101 F, pulse 112, blood pressure 98 systolic and 0 diastolic, total red cells 1,020,000, hemoglobin 37 Gm, reticulocytes 99 per cent, leukocytes 15,000. Immediately at the conclusion of the operation, at 1 a. m. the temperature was 101.6 F, pulse 132, blood pressure 106 systolic and 40 diastolic, total red cells 2,070,000, hemoglobin 60 Gm, leukocytes 34,000 with no immature myelocytes present, reticulocytes 89 per cent, erythrocyte fragility 0.707-0.412. Nine hours after the operation the reticulocytes had fallen to 68 per cent, at nineteen hours to 55 per cent and by the fourth day to 23 per cent thereafter showing a gradual but steady decrease to within the limits for normal by the thirty-eighth postoperative day. The blood platelets rose from a preoperative level of

the red blood cells, 688 microns, mean cell volume, 100 cubic microns, mean corpuscular hemoglobin, 32 micromicrograms, mean corpuscular hemoglobin concentration, 32 per cent, erythrocyte fragility, 0.582 to 0.300, corrected erythrocyte sedimentation, 0.6 mm per minute, icterus index, 882, white blood cells, 12,000, with 92 per cent neutrophilic leukocytes, 1 per cent basophils, 1 per cent small lymphocytes, 6 per cent monocytes, no immature forms, the blood was type AB. The urine was normal save for the high concentration of bile. The stools were of normal color and consistency and there was no occult blood. The direct van den Bergh test was immediately positive and the quantitative indirect test was 21 mg. The blood cholesterol was 197 mg, further confirming the relative quiescence of the hemolytic process. Wassermann and Kahn reactions were negative and remained consistently so. The electrocardiographic studies revealed no significant cardiac abnormality. On roentgen examination a small annular shadow about 1 cm in diameter, was discernible just to the right of the upper part of the third lumbar vertebra, the gallbladder was nonfilling.

During the next forty-eight hours the red count fell to 3,000,000, the hemoglobin to 11 Gm, the reticulocytes rose gradually to 14.2 per cent, and the icterus index decreased appreciably to 652, 555 and 428 and then started to rise again to 440.

The observations thus indicated an icterus of double origin, first an older fairly quiescent congenital hemolytic form, with splenomegaly, and, secondly, a recent acute, obstructive form, due to common duct stone. Since some 70 per cent of patients with hemolytic icterus are known to develop pigment calculi in the gallbladder, such an incident as described is easily explained and may be anticipated in these patients. The hemolytic factor in the beginning was negligible, but, as frequently happens, the trauma incident to the obstructive symptoms began to activate the hemolytic process. Two courses of management had therefore to be considered: (1) immediate splenectomy, to stop an impending erythroclastic crisis, or (2) a prior cholecystostomy, in the attempt to relieve the acute cholemia and prepare the way for a safer hemostasis in whatever major operative procedures might be required subsequently. The relatively good level of red cells and hemoglobin, with as yet little evidence of severe hemolysis determined our decision to follow the second course, hoping that the anticipated precipitation of an acute hemoclastic crisis might be delayed long enough to permit of a subsidence of the major part of the obstructive element in the jaundice.

On the night before, and again on the morning of operation the patient was prepared for laparotomy by the intravenous administration of 5 Gm of calcium chloride in 200 cc. of physiologic solution of sodium chloride and by a hypodermoclysis of 1500 cc of Ringer's solution containing 5 per cent dextrose.

Cholecystostomy was accomplished uneventfully under local anesthesia supplemented by nitrous oxide oxygen between 10 a m and noon December 7.

Prompt and rapid relief from the cholemia ensued. By the afternoon of the day of operation the icterus index had dropped to 250 the next morning it was 164, and forty eight hours after the operation it was 94. However, during the first thirty-six hours the erythrocytes decreased a million cells and the hemoglobin 3.7 Gm, while the reticulocytes rose coincidentally to 20 per cent. Frequently repeated observations confirmed the acuteness and the severity of the erythroclastic crisis, which had been threatened by the original spontaneous obstruction and which, by the manipulation and trauma incident to the operation, had become fully precipitated. The red cells continued to fall rapidly to reach a low of 1,610,000 by 9 p m. December 9, the hemoglobin fell to 3.9 Gm and the cholesterol to 130 mg, at which time the icterus index had ceased to fall and had begun to rise again from 94 to 125 within seven hours. A sharp change in the clinical picture occurred and it was apparent that a fatal outcome threatened unless adequate measures were promptly instituted. Transfusion was definitely contraindicated. From the experiences already cited it seemed evident that splenectomy was the only rational measure to employ to arrest this unusually severe though anticipated

hemolytic complication, and it was felt that we could reasonably count on the customary postsplenectomy autotransfusion in the convalescence, if the operative procedure itself was safely accomplished.

The patient was prepared immediately, therefore, for his second major operation within sixty hours with calcium, dextrose and fluids, as before. At 10 p m, December 9 just fifty-eight hours after the cholecystostomy, an emergency splenectomy was successfully performed under local and nitrous oxide-oxygen anesthesia. Epinephrine, 1 cc., was administered twenty minutes before the splenic pedicle was clamped to ensure maximum contraction of the organ. The spleen was removed through a left subcostal Kocher incision without undue difficulty or untoward incident. The blood pressure remained around 140 systolic, 50 diastolic, throughout the procedure and prompt postanesthetic recovery followed.

The spleen weighed 1,740 Gm and measured 22 by 15 by 9 cm. It was firm and contracted. The white opaque capsule was in some places as thick as 4 mm. The splenic parenchyma was dark red, cellular, somewhat friable and more fibrous than normal. Microscopically the pathognomonic picture of hemolytic icterus, including infrequent atrophic follicles, erythrocytic engorgement, prominent endothelial nuclei and clasmatoocytes, and empty sinuses, was confirmed.

Immediately on the removal of the spleen the unfavorable course of events of the preceding forty-eight hours was strikingly changed. The red cells immediately after operation jumped to 2,380,000 (a gain of approximately 800,000), with the hemoglobin 6.6 Gm (a gain of 2.7 Gm). The icterus index again showed a downward trend with a reading of 100. These results and the other clinical and laboratory data were doubly significant in that they not only reflected an actual, almost instantaneous, increased availability of important cellular elements essential to the vital functions of the body but at the same time revealed as a part of the mechanism of accomplishment of that end the abrupt termination of the fulminating hemolytic process which had so rapidly plunged the patient into extreme danger. The steady upward trend of the red cells and hemoglobin from this point, the prompt return of the reticulocyte percentage and icterus index to normal, and the leukocytic reaction may be followed in chart 4. At no time in the subsequent stormy convalescence (cholecystoduodenostomy and lung abscess) was the hemolytotoxic equilibrium again seriously disturbed, the bone marrow meeting all demands promptly and efficiently as they arose, without any evidence of decompensation or incapacity.

THROMBOPENIC PURPURA

The similarity and dramatic suddenness with which certain types of acute, fulminant thrombopenic purpura can be arrested by emergency splenectomy have led us to incorporate one such instance, which has come under our immediate care, in this communication. Our chief interest throughout these studies of the past decade, whether they have been animal experiments or human clinical problems, has been the further understanding of the pathologic physiology of the spleen. This organ has been amply demonstrated to contain within itself the potential sources for inhibition of marrow hematopoiesis or/and the sequestration and destruction of the circulating elements of the blood emanating from the marrow. The same fundamental considerations apply, therefore, whether the chief pathologic manifestation of such activities is reflected primarily in red cells, in the platelets or in the granulocytes.

While accepted as a procedure of some promise in the more chronic thrombopenic states, the question of the safety and rationale of splenectomy under the critical circumstances attending an acute thromboclastic crisis continues to be debated, even as in hemolytic jaundice. The consensus of the best surgical opinion at the moment seems to be against operation

except in those instances in which some degree of chronicity exists, or may, by medical means, be induced⁹

CASE 4 (charts 2 and 5)—E. M., a Negro girl, aged 17 years, was admitted to University Hospital as a transfer from another hospital, June 23, 1934, with the diagnosis of aplastic anemia with symptomatic purpura

The laboratory studies showed an anemia of 1,770,000 red blood cells, hemoglobin 4.9 Gm (Newcomer), color index 0.9, reticulocytes 57 per cent, erythroblasts 1,200, normoblasts 2,400 per cubic millimeter, mean erythrocyte diameter 8.6 microns with both anisocytosis and poikilocytosis extreme on direct examination but with no "sickling," immediate or delayed, erythrocyte fragility was markedly decreased, hemolysis starting at 0.319 and not complete until something less than 0.210 salt equivalent, icterus index 6, leukocytes 30,000, with 67 per cent actively motile, mature, neutrophilic granulocytes, 5 per cent myelocytes C and metamyelocytes, 1 per cent eosinophils, 18 per cent lymphocytes, 9 per cent monocytes, blood platelets 3,500, bleeding time twenty-three minutes, coagulation time (Howell) eleven minutes, calcium time twelve minutes, prothrombin time twelve minutes, no clot retraction in twenty-four hours, tourniquet test (50 mm of mercury) showed innumerable petechiae after ten minutes. The Wassermann and Kahn tests were negative, carbon dioxide combining power 36 blood group O. Blood cultures were negative. The daily temperature fluctuation ranged from 99 F to 104 F.

In spite of intensive medical treatment—intramuscular whole blood 50 cc. within the first twenty-four hours and 500 cc intravenously during the second day, electrical cauterization of the cervical canal with firm packing, oral hygiene, orange juice 1 pint three times a day, viosterol 10 minims (0.6 cc.) three times a day¹⁰ and a high fat-protein diet¹¹—the total red blood cell count fell rapidly until on the morning of the fourth day it was found to be only 725,000, hemoglobin 2.4 Gm, nucleated red cells 6,000, reticulocytes 30 per cent and leukocytes 25,000, with absolutely no blood platelets to be found (chart 5). The patient was comatose and moribund. An emergency transfusion of 700 cc of blood at 11 a. m. raised the red count to 1,230,000, another of 400 cc was given at 7 p. m. the same day. The blood count at 7.45 the next morning, June 28, showed erythrocytes 1,660,000, hemoglobin 4.9 Gm, leukocytes 10,800, blood platelets, 0. The clinical condition of the patient was the best it had been since admission, temperature 99.6 F, pulse 88, respiration rate 24, blood pressure 100 systolic, 58 diastolic. The mentality was clear, the patient was bright and responsive. It was decided thereupon to resort to surgery without further delay, a ligation of the splenic artery¹² to be attempted if splenectomy for any reason seemed inadvisable.

Under local procaine hydrochloride and nitrous oxide oxygen anesthesia a spleen weighing 225 Gm was removed without difficulty and with a minimum loss of blood. At the conclusion of the operation the pulse was 96, respiration rate 24, blood pressure 140 systolic, 90 diastolic, red blood cells 1,990,000, reticulocytes 15 per cent, hemoglobin 5.9 Gm, leukocytes 14,800, blood platelets 21,900. The maximum leukocyte count of 52,000 with 85 per cent active mature neutrophils was reached twenty-four hours after operation, the red cells at that time being 2,230,000, hemoglobin 6.2 Gm and blood platelets 89,000, with all bleeding stopped.

The blood platelets, showing a marked variation qualitatively in individual size, increased steadily in number on every count after operation until a total of 395,000 was reached on the fourth postoperative day, following which there was a gradual fall during the next eight days without symptoms or signs. A spontaneous recovery carried the total to 748,000 by the twenty-second postoperative day. The condition of the mouth cleared

promptly with the cessation of the hemorrhages, the offending molar was extracted on the fifteenth postoperative day, and the teeth and gingivae were given much needed attention. The red cells never again fell below 2,000,000, the reticulocytes promptly decreased, and both hemoglobin and cell count rose gradually until on the twentieth day 3,400,000 erythrocytes were recorded. The bleeding time became normal, clot retraction occurred promptly and the tourniquet test was negative for petechiae after ten minutes at 50 mm pressure of mercury. The temperature and pulse returned to within normal limits by the ninth day and the patient was discharged from the hospital on the twenty-second postoperative day.

The patient has maintained an entirely normal existence for the past year, with the platelet count maintained at or above a million units per cubic millimeter consistently (chart 5).

CONTROL OBSERVATIONS

The influence of any major surgical procedure and of anesthesia on the cellular equilibrium of the blood and on the blood producing and blood regulating mechanisms of the body must be known before any specificity may be attributed to the changes noted following splenectomy. In chart 1 it will be noted that in two of the patients with hemolytic jaundice other major operative procedures were carried out.

In chart 4 the influence of cholecystostomy before and of cholecystoduodenostomy after splenectomy may be compared in the same individual. Only following splenectomy were the spectacular recovery changes in the hemolytopoietic equilibrium apparent, a precipitous hemoclastic crisis being stopped instantly with removal of the spleen, just fifty-eight hours after a major operative procedure in the opposite abdominal quadrant.

Chart 6 carries the cytologic changes in fourteen cases in which operation was done for a variety of conditions, and illustrates the lack of uniformity in the degree and the direction of the reactions.

It would seem fair to conclude that the removal of the spleen removes certain inhibitory and destructive influences which ordinarily affect all the circulating units, including the lymphocytes, which, after a latent period of some two weeks, definitely seek a new and higher level in the circulation. The surgical removal of other body structures does not seem to influence the cellular equilibriums of the blood to the same extent.

A million gain the first twenty-four hours, with the consolidation of the gain during the first week, the second million gain by the end of the first month, and, following that, a more or less rapid ascent to an absolutely normal erythrocyte level is the story depicted in chart 2 for the six individuals who have undergone emergency splenectomy as described.

ETIOLOGIC CONSIDERATIONS

Our studies of the past five years have led us to incriminate the spleen as the major pathologic agent in hemolytic jaundice for the following reasons: 1 Qualitative changes in the erythrocytes—microcytosis, increased reticulocytosis and increased fragility—are not necessarily present in every clinical case, even with acute symptoms. 2 Anemia, when present, is always accompanied by acholuric jaundice or other evidence of excessive hemolysis. 3 The more severe the anemia the greater the bone marrow activity, as measured either by reticulocytosis (usually the higher the reticulocytes the more severe the hemolysis) or by direct observations of erythroblastic hyperplasia of the bone marrow. 4 Splenomegaly, and the number and activity of the splenic phagocytes, fluctuates directly with the severity of the anemia and the icterus. 5 The splenic artery, in several instances of sampling just prior to

Chir.* 167: 512 1931.

ligation, contained more cellular elements than the splenic vein. 6 The epinephrine test reveals an excessive cellular sequestration capacity of the spleen in congenital jaundice. The data accumulated following splenectomy further support this thesis in that 7 Hemoclastic crises, spontaneous or precipitated, may be terminated instantly by successful removal of the spleen and do not recur. 8 The total volume of circulating red blood cells becomes immediately increased, as much as 77 per cent of the original volume. 9 A normal erythrocyte equilibrium is reestablished and indefinitely maintained, with 10 Restoration of a relatively normal bone marrow—functionally and topographically—as reflected by the reduction to normal of the erythroblastic hyperplasia, the disappearance of the high peripheral reticulocytosis, the recovery from the myeloid hypoplasia with correction of the peripheral neutropenia, the elimination of the megacaryocytic hypoplasia or hypofunction with reversal of the peripheral thrombopenia and the maintenance of an elevated thrombocytosis, the return of the erythrocyte diameters (Price-Jones curves) more nearly to the established limits for normal, a decrease in the erythrocyte volume-thickness index (Haden), and the increase in erythrocyte resistance sometimes to an entirely normal range, and finally, 11 The clinical recovery is complete and permanent so far as the hemolytic tendency is concerned.

The facts that relate to the pathologic physiology of the spleen as inferred from this study may be applied in other instances to appraise the significance of the spleen in less clearly defined syndromes. The objective in all analyses of biologic problems should be an understanding of the underlying mechanisms involved, and all therapy should be directed toward a correction of, or, as in this instance, to the elimination of the dysfunctioning unit. Once the physiologic mechanism is understood and the technical facilities for testing its efficiency and adequacy are available, the physician may hope to place his therapy on a rational basis.

CONCLUSIONS

1 The pathologic physiology of the spleen may be manifest through either or both of two mechanisms (a) inhibitory, (b) destructive—and may affect any or all of the circulating blood elements.

2 The spleen is the major pathologic agent in congenital hemolytic jaundice.

3 Splenectomy is indicated as a prophylactic measure against clinical exacerbations of excessive hemolytic activity in the chronic and subacute manifestations of the disease.

4 Splenectomy is also the therapeutic procedure of choice in acute hemoclastic crises, whether the crisis is of spontaneous or of precipitated origin, and regardless of the severity of the anemia.

5 The immediacy of the erythrocyte response following splenectomy in hemolytic jaundice is dramatic occurring on the operating table. It is usually a million or more cells per cubic millimeter in quantity and represents a true increase in total available circulating units. This autotransfusion removes the necessity for preoperative and/or postoperative transfusions.

6 Splenectomy is not contraindicated in properly selected cases of thrombopenic purpura in acute crisis provided adequate preoperative blood transfusions are given. The immediacy of the beginning recovery and reappearance of blood platelets in the circulation fol-

lowing splenectomy in thrombopenic purpura may be quite as dramatic as the changes noted in hemolytic jaundice.

7 The responses recorded following splenectomy in this series are not the result of the operative or anesthetic influences per se, since the same studies in a series of miscellaneous operations performed under identical conditions did not yield similar results. More impressive still, three major operative procedures other than splenectomy were performed either before or after splenectomy in two patients with hemolytic jaundice, and the cellular responses were quite unlike.

We are indebted to Drs. Verne Dodd and Luke Zartman for the splenectomies in cases 1 and 2 and to Dr. Carl Moore, National Research Council Fellow in this department, for the blood volume studies, also to Drs. Lowell Erf and M. M. Hargraves, medical residents, and to Dr. Louis Barron, surgical resident in the Research Service, University Hospital, for assistance and cooperation in the care of certain of the patients in this series.

ABSTRACT OF DISCUSSION

DR IRVIN ABELL, Louisville, Ky. I was particularly impressed by the advocacy by the authors of immediate splenectomy in hemolytic and purpuric crises, a course diametrically opposite to that which heretofore has been thought the wisest to follow. In the light of their results the proposal merits one's earnest consideration. Advantage has been taken of the reservoir function of the spleen and the fact that it can be made to empty itself by the injection of epinephrine, to prevent the loss of its stored blood during splenectomy. After the incision has been made and the spleen exposed, an injection of epinephrine is given causing the organ to contract, forcing its contained blood into the general circulation and at the same time effecting a decrease in size and an increase in consistency that may facilitate its removal. Complete and repeated blood studies constitute the essential factor in deciding for or against operation and, in the event of the former, in determining the time of its performance.

DR G. M. CURTIS, Columbus, Ohio. During the last thirty-two months I have performed twenty-seven splenectomies for various blood diseases. The blood picture has been followed thoroughly previous to, immediately after and subsequent to removal of the spleen. The outstanding success has been in congenital hemolytic icterus. These patients have all survived. My outstanding failure has been in attempting splenectomy for late Banti's disease. Owing to extensive adhesions and unusual vascularity, this is a technically difficult and hazardous procedure. Occasionally in hemolytic icterus the enlarged spleen is adherent to the diaphragm. However, a useful cleavage plane may be found between the thickened capsule and the pulp. This is not possible in Banti's disease, since the sclerosis involves the connecting capsular trabeculae. It is the usual teaching that the acute hemoclastic crisis of congenital hemolytic icterus and the acute thromboclastic crisis of thrombocytopenic purpura contraindicate splenectomy. This is not my experience. I have made three splenectomies for the acute crisis occurring in congenital hemolytic icterus. My colleagues have made two more. I have made one splenectomy for the acute crisis of thrombocytopenic purpura. These six patients recovered, are all living and are well. The rationale of this departure from the common teaching followed a cooperative study with my colleagues Doan and Wiseman. Following our first splenectomies there ensued a definite and immediate postoperative rise of the red cells and of the hemoglobin. Dr. Doan has presented those data. This amounted essentially to an autotransfusion. The evidence became convincing that the spleen is primarily responsible for the increased blood destruction. Therefore when an acute crisis came it seemed logical to remove the spleen. From our previous studies we depended on a postoperative autotransfusion. In certain cases of failure after splenectomy for congenital hemolytic icterus or for thrombocytopenic purpura, we would advise searching for an accessory spleen. We find them in making these splenectomies. Therefore it is reasonable to assume that

when the symptoms recur they may be due to an accessory spleen. These results consider a further indication for splenectomy. They afford added hope in the control of severe hemoclastic crises and throw more light on the pathologic physiology of the spleen. This newer information should prove of value in evaluating the fundamental rule of the spleen in blood dyscrasias.

DR. B. K. WISEMAN, Columbus, Ohio. My feeling with regard to hemolytic icterus is that all these patients should be operated on as soon as the diagnosis is made. Many, probably most, of these patients show little of the external manifestations and not very much of the hematologic characteristics of their disease. Under such circumstances it is often the practice to defer splenectomy with the hope that possibly the operation will not be necessary. Because of the tendency of this disease to change from one of perhaps extreme chronicity to the acute phase with alarming and dangerous features on the advent of a primary infection, it often follows that operation must be then performed under most unfavorable conditions. In some circumstances this occurs in a remote region in which the underlying condition will not be recognized readily. Dr. Doan has shown that there is no doubt that emergency splenectomy can be done and is a life-saving measure (contrary to common belief) during an acute hemolytic crisis. Nevertheless the added factor of extensive hemolysis, together with in some cases the presence of the affliction that precipitated the crisis, adds a definite hazard to the chances of survival. Early operation in Banti's disease is also, I feel, very important. Of all the blood dyscrasias, Banti's disease is perhaps the most difficult to diagnose especially in the early phases. It therefore seems advisable at times to operate before a positive diagnosis can be made. Operated early, before cirrhosis of the liver is advanced, portal obstruction is evident or dense perisplenic adhesions are formed, it is attended by the usual low surgical mortality, and the maximal benefit accrues to the patient. Therefore it will often be necessary to operate on a well founded suspicion and not a clear cut diagnosis. With the possible exception of myeloid leukemia, there is no blood dyscrasia that we have found to be unfavorably affected by splenectomy.

DR. WILLIAM DAMESHEK, Boston. I was particularly interested in the marked almost immediate increase in red cell count following splenectomy mentioned by the authors. I wonder whether this might not be due to unavoidable handling of the spleen which takes place at time of operation. The normal spleen contains about 250 cc of blood. In congenital hemolytic jaundice the spleen becomes very much enlarged and the splenic sinusoids are dilated, therefore it must contain a much larger quantity of blood. The sudden increase in red cell count might conceivably be due to squeezing out into the general circulation of a fairly large volume of blood from the spleen. The list of reasons given in the article for implicating the spleen as the fundamental cause for congenital hemolytic jaundice is an imposing one, but several of them may be secondary to the fundamental bone marrow dysfunction stressed by several authors, particularly Naegeli and Haden. These investigators have shown that the bone marrow in this disease produces abnormally small thick (and thus more fragile) red cells susceptible of ready disruption and fragmentation. The spleen, together with the remainder of the reticulo endothelial system, becomes hyperplastic, probably as the result of the increased amount of activity demanded of that organ in breaking down an increased number of red cells. Some of the phenomena listed by the authors may thus be secondary to this hyperplasia of the reticulo endothelial system (and spleen) rather than primary manifestations. In purpura one should be very conservative regarding splenectomy, even though it cannot be denied that this procedure will result in great improvement. A number of our patients with splenectomy are beginning to bleed years later. Before finally deciding on this major operative procedure, one should always attempt to do everything possible in the way of conservative medical treatment, such as high vitamin, high protein diet, and roentgen therapy over the spleen.

DR. E. B. KRUMBHAR, Philadelphia. The spleen is undoubtedly the major offender in hemolytic jaundice, and this constitutes an excellent reason for taking it out. On the other hand, I think perhaps Drs. Doan, Curtis and Wiseman would

agree that the primary defect is in the red cells for the reasons that Dr. Dameshek gave. It may be that there is also a primary defect in the spleen, or it may be that the spleen acquires the role of chief offender from long practice in destroying these futile, congenitally poor red cells of hemolytic jaundice. Undoubtedly, when the spleen of hemolytic jaundice is taken out there is a substantial rise, often very quick, in the erythrocyte level, but I would call attention to the possibility at least (I think it is more than a possibility) that the spleen normally aids in red blood cell formation. Because a diseased spleen has been taken out, it must not be inferred that the role of the normal spleen is one of inhibition of red cell formation. I have been studying this for several years and still stand by the conclusion that the normal human spleen has a stimulating effect on the bone marrow in ways that are not yet apparent, perhaps associated with the metabolism of broken-down red cells and some of their products. At any rate, if a normal spleen is taken out, there will be a period of temporary depression of bone marrow activity with temporary anemia, which eventually will be compensated for just as most of the functions of the absent spleen will be compensated for by other parts of the reticulo-endothelial system.

DR. C. A. DOAN, Columbus, Ohio. I realize the departure from accepted facts that my observations imply, and the rightful skepticism aroused by certain of my conclusions, and were it not that I have observed multiple repetitions of the same phenomena over a period of five years, I should not feel justified in reopening some of the questions that have been raised. Banti's disease is admittedly difficult to influence favorably in its later stages, and in three instances in this series splenectomy was unsuccessful. In two early cases, however, the immediate and remote results have more than justified the operative intervention. I may not have made it sufficiently clear that in the patients with acute hemoclastic crises splenectomy was advised, at the beginning of this study, only in the face of failure of other less radical measures. Intensive liver therapy, adequate iron and repeated blood transfusions preceded operation in practically every instance without beneficial effect. More recently I have not risked delay in the face of a crisis. The idea is prevalent that removal of the spleen is incompatible with longevity. I well remember seeing the first patient ever operated on in this country for hemolytic jaundice, for twenty five years shown annually by Dr. Thayer before the senior clinics at the Johns Hopkins Hospital. The patient, an invalid during the first twenty-five years of his life, was completely rehabilitated after splenectomy and remained in excellent health for the succeeding quarter of a century. Four years ago Lord Dawson reported that a number of patients with congenital hemolytic jaundice, splenectomized prior to 1914, went through the war without physical limitations or handicap. The spleen is not essential to life, conversely, it may at times be exceedingly dangerous to existence. The mechanism of the prompt increase in the cellular level following splenectomy has been demonstrated adequately in the blood volume studies. Both an absolute increase in circulating units and some decrease in plasma volume contribute to the immediate phenomenon. An unusually active bone marrow thereafter maintains and supplements this initial gain and rapidly and effectively reestablishes the normal cellular balance in the absence of the pathogenic spleen. This interpretation, of course, introduces the controversial point as to the relative roles of bone marrow and spleen in hemolytic icterus. I have already presented my reasons for believing the spleen to be the chief offender in this disease. I would reemphasize the necessity for the closest possible cooperation between the hematologist and the surgeon in the diagnosis and therapeutic management of these cases. Only by the intelligent analysis of each patient as an individual and a full understanding of the mechanism of the disease process, as it is reflected in certain constantly changing signs and symptoms, may optimal clinical results be expected.

Blood Pressure—If a patient has diseased arteries a small rise of blood pressure may be very important from the point of view of possible cerebral hemorrhage.—Dr. Maurice Campbell, F.R.C.P., quoted by Fisher, *Aphorisms in Clinical Medicine* *Canad J Med & Surg* 77 166 (June) 1935.

THE CHOICE AND INTERPRETATION OF
TESTS OF RENAL EFFICIENCY

R H FREYBERG, MD

ANN ARBOR, MICH

The importance of measuring the functional ability of the kidneys in renal disease need not be emphasized. The value of a knowledge of renal efficiency as an aid in the diagnosis, prognosis and treatment of Bright's disease has been pointed out by Christian,¹ Van Slyke² and others. The existence of renal disease, which may be suggested by proteinuria or other changes, may often be proved only by demonstrating impairment of kidney function. Van Slyke and his collaborators² call attention to the fact that the degree of proteinuria, hematuria and hypertension is no indication of the severity of the renal lesion and is of little or no prognostic importance, but that the functional capacity of the kidneys is an accurate index of the gravity, course and prognosis of Bright's disease. Lashmet and Newburgh³ have pointed out that the degree of functional impairment governs the fluid needs of the nephritic patient, one of the most important therapeutic considerations.

It becomes of great concern, therefore, to know how best to measure renal efficiency. All the numerous methods proposed are based on one of three principles: (1) the ability of the kidneys to concentrate and dilute urine, (2) the effectiveness of the kidneys in eliminating introduced substances, such as phenol-sulphonphthalein, and (3) the success of the kidneys in excreting normal metabolic waste products, which can be studied by comparison of the urinary and blood values of the various waste products (so-called clearance tests) or by determining the concentration of these wastes in the blood.

During the past few years I have been occupied in determining the relative worth of various kidney function tests, based on these different principles.

METHODS

Whenever it was desired to determine renal efficiency, three procedures were employed, each based on a different one of the three principles. The concentrating ability of the kidneys was measured by the method described by Lashmet and Newburgh.⁴ The urea excreting ability was measured by the urea clearance test of Van Slyke because of the widespread usage of this test and its already demonstrated worth. The fifteen-minute phenolsulphonphthalein excretion test was used to measure the efficiency of dye elimination for the following reasons. It has been shown by Van Slyke⁵ and others that the total two-hour phenolsulphonphthalein excretion test measures impairment of kidney function only when extensive renal damage exists. Recently, Chapman and Halstead⁶ have pointed

out that the excretion of this dye during the first fifteen minutes after its injection is a much more sensitive test and, in their experience, comparable to the urea clearance as a measure of renal efficiency.

Because it has been clearly shown by a number of investigators that retention of catabolic waste products does not occur as a result of kidney damage, except when the renal injury is severe, blood nonprotein nitrogen and blood urea determinations were not made as a routine.

With these three procedures in each case, then, the Lashmet-Newburgh concentration test, the Van Slyke urea clearance, and the fifteen-minute phenolsulphonphthalein excretion, renal efficiency was measured 412 times in 254 different patients whose clinical diagnoses included hemorrhagic nephritis (with and without the "nephrotic syndrome"), arteriosclerotic Bright's disease, pyelitis, pyelonephritis, tuberculous kidney disease, polycystic kidney disease, renal amyloidosis, pregnancy, and other clinical conditions in which impairment of kidney function was suspected.

Technical Considerations—Specific gravity of the urine was determined by a carefully calibrated urin-

out that the excretion of this dye during the first fifteen minutes after its injection is a much more sensitive test and, in their experience, comparable to the urea clearance as a measure of renal efficiency.

ometer during the early part of this study and later by a special Westphal balance. Since only the non-protein specific gravity indicates the concentrating power of the kidneys, proteinuria was quantitatively determined and the nonprotein specific gravity obtained from the observed specific gravity according to the method described by Lashmet and Newburgh.⁷ Whenever concentrating ability of the kidneys is referred to hereafter, nonprotein specific gravity of the urine is implied.

The urea clearance was determined by the simplified technic described by Van Slyke and Cope.⁸

To test dye excretion, 6 mg of the sodium salt of phenolsulphonphthalein was injected intravenously and the amount in the urine determined by color comparison (in a colorimeter) with a standard freshly prepared from the same lot of dye injected into the patient.

All technical procedures were performed by only two individuals, so that personal variations might be lessened.

Normal Values—Under the conditions of the concentration test, the specific gravity of the urine should reach 1 029, or higher. When the maximum specific gravity is less than 1 029, impairment of function is indicated. Blood urea clearance is reported in per cent of mean normal. The interpretations of the originators of this test have been adopted to consider values between 75 and 125 per cent as normal, values greater than 125 per cent as indicating hyperfunction, and

to concentrate normally. Is this the result of technical errors in performing the concentration test, or is this an indication that the ability of the kidneys to excrete a concentrated urine is impaired before the urea excreting power is recognizably diminished? The answer to this is quite evident after studying the data presented in table 1. During the initial stage of hemorrhagic nephritis it has been repeatedly observed that the concentrating ability is impaired before the urea clearance is measured below normal (cases B B and B L) and likewise, during recovery from hemorrhagic nephritis, the urea clearance becomes normal while the concentrating ability is still impaired (cases D S, L S, E M, J J and G H). I have observed, as have Alving and Van Slyke,⁹ that the maximal specific gravity of the urine may remain below normal for years after recovery of normal urea clearance. That the urine contains abnormalities (protein, casts and erythrocytes) in cases showing impaired concentrating ability and normal urea clearance, both in initial stages and recovery periods, indicates that these kidneys are not normal. There can be no doubt, therefore, that the concentration test is a more sensitive measure of functional ability in these cases than is the urea clearance.

Chart 1—A comparison of the urea clearance (left) and the fifteen minute dye excretion (right) with the concentrating ability of the kidneys in cases of hemorrhagic nephritis. Circles indicate results in cases without edema and the dots show results in patients with the nephrotic syndrome. The line in each graph represents the average urea clearance and the fifteen minute dye excretion respectively, in terms of the maximum nonprotein specific gravities obtained in concentration tests.

values below 75 per cent as indicating a renal deficit. Chapman and Halstead found the lowest fifteen-minute dye excretion by normal individuals to be 28 per cent, and I found it to be 29 per cent. The excretion of less than 28 per cent of the injected dye during the first fifteen minutes is therefore considered to indicate impairment of this function of the kidneys.

RESULTS

In chart 1, the blood urea clearance and fifteen-minute dye excretion are compared to the concentrating ability of the kidneys in cases of hemorrhagic nephritis. There is seen to be quite close parallelism between these different functions of the kidneys. In general, as the kidneys lose their ability to excrete concentrated urine, their urea excreting and dye eliminating function also becomes impaired. The line drawn in each graph shows the average urea clearance and dye excretion at different levels of concentrating ability. When the kidneys are able to concentrate urine to a specific gravity of only 1 025, the average urea clearance is 62 per cent, although the range is seen to be from 50 to 96 per cent. When the concentrating ability has fallen to 1 015 the average urea clearance is 28 per cent, and the range from 20 to 33 per cent. When the specific gravity is fixed at 1 010, the average urea clearance is 12 per cent, although it may range between 10 and 25 per cent. Although it may appear that there is quite a wide variation between the results of the tests studied, when one realizes that these tests are based on entirely different principles and measure totally different functions of the kidneys, it seems quite remarkable that there is the degree of parallelism that has been found.

When the relationship between the concentrating ability of the kidneys and the urea clearance in hemorrhagic nephritis (left-hand graph, chart 1) is carefully studied, several noteworthy facts become evident. In the first place, it is seen that whereas there are only two individuals able to concentrate the urine normally who failed to excrete urea normally, there are twelve individuals with normal urea clearance who were unable

As more and more renal damage occurs, it is seen that the concentrating ability and the urea clearance decrease quite in parallel until extreme renal damage exists. Then the specific gravity of the urine tends to become fixed at about 1 010 and further damage is not reflected by a decrease in concentrating ability but is indicated by a continual decrease in urea clearance. In one case it was observed that the specific gravity of the urine remained fixed while the urea clearance progressively fell from 15 to 3 per cent of normal, at which level death occurred.

When the fifteen-minute dye excretion is compared with the concentration test (right-hand graph, chart 1),

Chart 2—Urea clearance plotted against fifteen minute dye excretion in cases of hemorrhagic nephritis. The line represents the average urea clearance in terms of different percentage dye excretion.

it is seen that, although in general they give comparable results, the deviation from the average is wider (greater scatter in the graph). Reasons for this will be discussed in full.

In chart 2, the results of urea clearance are compared to those of the fifteen-minute dye test, in cases

⁹ Alving, A., and Van Slyke, D. D. The Significance of Concentration and Dilution Tests in Bright's Disease. *J. Clin. Investigation* 13: 969-998 (Nov.) 1934.

of hemorrhagic nephritis Here again there is a wide variation of results, especially when only mild or moderate renal damage exists

The results in patients with arteriosclerotic Bright's disease are shown in chart 3 The urea clearance and concentrating ability are seen to differ more in these patients than in cases of hemorrhagic nephritis The most important observation is that, whereas only four cases show impaired urea excreting ability (and three

these tests in this miscellaneous group of clinical entities is demonstrated by the general parallelism of the results

THE UREA RATIO

Within the past year, Mosenthal and Bruger¹⁰ have reported that the urea ratio (the percentage of the nonprotein nitrogen which is urea nitrogen, i e, $\frac{100 \times \text{urea nitrogen}}{\text{nonprotein nitrogen}}$) is a satisfactory index of renal efficiency These investigators point out that the urea ratio is a correct indication of kidney function even though the concentrations of both urea and nonprotein nitrogen in the blood are within normal limits Their report shows excellent agreement between the urea ratio and the urea clearance This method is most attractive, since it requires only one sample of blood in order to obtain the result

During the past few months the urea ratio has been employed along with the other procedures mentioned The results are shown in table 2 The general parallelism of results is evident Patients J R, C D, and S L show normal urea ratios, when other tests show impairment of renal function This lack of agreement may be due to differences in technique¹¹ This brief experience with the urea ratio has encouraged me to plan a careful comparative study of this test, using the chemical procedures employed by Mosenthal

CONDITIONS INVALIDATING THE VARIOUS TESTS

Even when the technical manipulations are satisfactorily executed, tests of renal function may fail to measure truly the renal efficiency The most important conditions that tend to falsify results are noted farther on

Concentration Test—When the concentration test is employed as described by Lashmet and Newburgh, the only clinical condition found to invalidate the results is the presence of edema held loosely in the body tissues Even though fluid is withheld from the patient, the urine may be diluted by the excretion of edema and

Chart 3—A comparison of the urea clearance (left) and the fifteen minute dye excretion (right) with the concentrating ability of the kidneys in cases of arteriosclerotic Bright's disease. The line in each graph represents the average urea clearance and fifteen-minute dye excretion respectively in terms of maximum nonprotein specific gravities obtained in concentration tests

very slightly) together with normal concentrating ability, thirty-eight cases are seen to present impaired concentrating ability together with normal urea clearance, and four cases show hyperfunction by urea clearance at the time when the concentrating ability is impaired Abnormal urine (proteinuria, cylindruria and occasionally hematuria) was found in all but a few of this group So, even more frequently in arteriosclerotic Bright's disease than in hemorrhagic nephritis is the concentration test a more sensitive indication of functional impairment It should be noted that the majority of these cases show less severe renal damage than do patients with hemorrhagic nephritis When more extensive renal damage exists, the two tests parallel each other more closely

When the fifteen-minute dye excretion is compared with the concentrating ability (right-hand graph, chart 3), it is seen that there are twelve cases in which a low dye excretion was found together with normal concentrating ability Most of these patients had normal urea clearance and normal urine When the dye test was repeated, in many cases normal values were obtained These facts show that most of these low dye excretions are erroneous indications of renal function Eight cases showed normal fifteen-minute dye excretion, together with lowered concentrating ability, but (except for one case) the specific gravity was only slightly below normal All of the latter cases presented normal clearance Thus it may be concluded that when fifteen-minute dye excretion is normal the kidney function is normal (or the concentrating ability only slightly impaired) but that when low values are obtained for fifteen minute dye excretion they may not be true indications of renal function

In chart 4 are shown the results of kidney function studies that were performed on patients who were suffering from different illnesses in whom impairment of kidney function was suspected The applicability of

Chart 4—Results of renal function studies in patients with various illnesses other than hemorrhagic or arteriosclerotic Bright's disease, in whom tests were performed because of suspected impairment of renal function

have a specific gravity lower than the maximum that could be produced by the kidneys This is especially true in cases of congestive heart failure In patients with the "nephrotic syndrome" this error is less apt

Blood Urea Clearance Test—The accuracy of this test depends in part on measuring the urea excreted in the urine during an exact interval of time. The most important single factor tending to falsify results is the failure to obtain all the urine formed by the kidneys during the test. Prostatic obstruction, bladder diverticula, cystocele and incontinence usually account for these failures. They can often be prevented if the urine is obtained by catheter. When there is a constant amount of residual bladder urine, the urea clear-

ance is only slightly falsified because the urea excretion is compared with the concentration of urea in the blood, which varies but little during short periods of time.

The formulas used in calculating urea clearance contain a factor that corrects for variations in urea excretion at different rates of urine formation. However, when the urine flow is very small the urea clearance

calculated as usual fails to indicate the renal efficiency correctly. This is well demonstrated by the data in table 4, which shows urea clearance determined in the same subjects when the urine flow was small (during a concentration test) and within twenty-four hours later, when the urine volume was greater. It is seen that in most cases when the volume of urine is 20 cc. per hour or less the urea clearance is low.

Fifteen-Minute Dye Test—Besides the numerous opportunities for error in technic (quantitative injection, timing, and the like), the most frequent cause for false results with this test is again failure to obtain all the urine formed by the kidneys during this short interval of time. The error is usually of a much greater magnitude than in the urea clearance test, because the quantitative recovery of a substance not normally present in the blood and urine is required. Obtaining the urine by catheter will eliminate some but not all of the failures from this cause.

In a series of kidney function studies performed during the course of pregnancy, good agreement existed between the concentration and urea clearance tests, but low results were the rule with the fifteen

minute dye excretion in voided urine during the latter part of pregnancy (table 5). When the urine for the dye test was obtained by catheter, the results were in most cases no better (table 6). The explanation for this low dye excretion is no doubt a combination of several factors: additional circulation (fetal), altered blood flow through the kidneys due to the tumor of pregnancy, and the hydronephrosis known to exist commonly during pregnancy.

THE INTERPRETATION OF TESTS OF RENAL EFFICIENCY

How are the results of the various tests of kidney function to be interpreted? When the procedures for performing these tests are kept in mind, it is at once evident that only during the concentration test are conditions such that the kidney function is measured

while the kidneys are under functional strain. Consequently, this is the only test that is designed to measure maximal function. The results of this test tend to answer the question "How efficiently can the kidneys perform their function?" whereas the other tests tend to answer the question "How efficiently are the kidneys performing their function?" It is not surprising, then, that the concentration test registers impairment of function when other tests do not, and that it is therefore a more sensitive measure of renal efficiency. Furthermore, unless falsified by the urinary excretion of edema, low specific gravity of the urine obtained during a concentration test always indicates abnormality of the kidneys.

The urea clearance test measures the urea excreting ability of the kidneys under no strain. It is therefore less sensitive, but when impairment of urea excretion is found, except when the rate of urine formation is very slow (less than 20 cc per hour), it indicates renal abnormality.

Low fifteen-minute dye excretion theoretically should indicate renal abnormality, but in my experience the urine formed by the kidneys during this short period of time is so infrequently quantitatively recovered that I have come to interpret this test as follows. If the fifteen-minute dye excretion is normal, no appreciable

impairment of different functions of the kidney. For example, it is said that impairment of concentrating ability indicates tubular abnormality, for the normal function of the tubule is to reabsorb water and so concentrate the urine. In the present state of knowledge, it is my opinion that abnormal function, as demonstrated by clinical tests, cannot be interpreted in terms of specific renal pathologic changes.

not because of kidney disease but because of a nonrenal abnormality, in this case dehydration. Consequently, high blood urea, nonprotein nitrogen, and urea ratios do not necessarily indicate abnormality of the kidneys. Interpretation of these values requires a knowledge of the state of hydration of the body.

It has been suggested by a number of authors that various pathologic states of the kidney are indicated by

renal abnormality exists, however, if the excretion is below normal, the function should be checked by another test.

It has already been pointed out that a normal concentration of catabolic wastes in the blood does not necessarily indicate normal kidneys. A number of investigators have shown that extensive renal damage may exist and the blood urea and nonprotein nitrogen may still be within normal limits. Does abnormally high blood urea, nonprotein nitrogen or urea ratio indicate abnormality of the kidneys? This question is clearly answered by results of a controlled study of dehydration performed recently in conjunction with Drs Maddock and Collier.¹² During dehydration produced by the omission of fluids and the administration of a dry diet to a normal adult, various tests of renal function were performed. The data presented in table 7 show that during dehydration the blood urea progressively increased, thereby increasing the blood nonprotein nitrogen and the urea ratio until all three were well above normal limits, even though the kidneys were normal, as shown by the persistence of normal urea clearance and by the excretion of urine having a very high specific gravity. Inadequate renal function existed,

PRACTICAL CONSIDERATIONS

The training, equipment and time necessary to perform satisfactorily tests of renal efficiency involving quantitative chemical determinations practically limit the use of such tests to institutions. The independent practitioner of medicine has left only the concentration

test and the dye excretion tests. For reasons already mentioned, the test of choice in these circumstances is the concentration test, which can be performed with very little equipment and in a very short time.

SUMMARY AND CONCLUSIONS

This study demonstrates that the Lashmet-Newburgh concentration test is the only test which tends to

measure the maximal function of the kidneys, and for this reason it is the most sensitive test of renal efficiency, often demonstrating impairment of function when other tests fail to do so. This test does not require the quantitative collection of urine. Except when performed in the presence of loosely held edema, it always gives accurate results, and low specific gravities always indicate renal abnormality.

The urea excreting function of the kidneys, as measured by the urea clearance test, becomes impaired in many cases after the concentrating ability is diminished, so that the urea clearance is a less sensitive test of renal efficiency. Throughout the greatest part of the range of kidney function, the urea clearance and concentrating ability in general parallel each other. When the renal damage is severe, the specific gravity becomes fixed at a low level and the urea clearance alone indicates progression of the renal lesion. Failure to obtain quantitatively the urine formed by the kidneys during the urea clearance test will falsify the results. Low urea clearance always indicates renal abnormality, except when the urine volume is less than 20 cc per hour.

The two-hour phenolsulphonphthalein excretion is not a sensitive test of renal efficiency. Theoretically, the fifteen-minute dye excretion is a sensitive test of kidney function, but the obstacles to satisfactory execution of this test cause it to be unreliable. When a normal amount of dye (28 per cent or more) is excreted during the fifteen minutes after injection, one is safe in assuming that no appreciable renal damage exists. When low excretion is found, interpretation is hazardous.

Normal blood urea and nonprotein nitrogen may exist even when extensive renal damage is present, so that these values are poor indications of renal functional ability. Elevated blood urea, nonprotein nitrogen and urea ratio indicates only that the renal excretion of protein wastes is inefficient and does not necessarily indicate renal abnormality. Experience with the urea ratio has been too limited to allow an expression of opinion regarding the comparative value of this test as a measure of renal efficiency.

It is my opinion that, in order to have the most accurate and complete information regarding functional ability of the kidneys, the concentrating ability and the urea clearance should be determined.

University Hospital

ABSTRACT OF DISCUSSION

DR. HERMAN O. MOSENTHAL, New York. Impaired function of the kidney, as Dr. Freyberg says, is not a single process nor does it necessarily parallel the other disturbances in chronic interstitial nephritis, such as hypertension, albuminuria, edema or uremia. There are roughly four ways in which the activity of the kidney may be curtailed, and the tests for renal function, when properly interpreted, will reveal them. 1. A restriction in the urine volume, without loss of power of concentration of solids, signalized by a high specific gravity, a low percentage of phenolsulphonphthalein excretion, an elevation of the blood urea, an increase in the urea ratio and a lowering of the urea clearance, this occurs with heart failure, in acute nephritis and in chronic nephritis with edema formation. 2. A period of normal kidney function, with the exception that there is a low specific gravity indicating inability to concentrate the urine, which follows on the conditions mentioned under 1, that is, when the passive congestion, or the edema from whatever cause, diminishes and is lifted through polyuria. 3. The same is true, that is, a diminished ability to concentrate while elimination of solids is good, in the earlier stages of chronic interstitial nephritis, when there is nocturnal polyuria and the urinary specific gravity approaches 1.010 in a

fixed way, still, through the elimination of large amounts of fluid, the solids are eliminated, and that is why it is spoken of as a compensatory polyuria. That is why the low fixed specific gravity precedes the other signs of impaired renal function in chronic interstitial nephritis and why the specific gravity tests reach their maximal degree of impairment long before the other tests of renal function. 4. In the advanced cases of chronic interstitial nephritis, when only 10 per cent or less of the kidney tissue is functioning, according to urea clearance determination, there is both a low fixed specific gravity and an impaired elimination of solids, that is, the blood urea and the urea ratio rise while the urea clearance and the phenolsulphonphthalein excretion diminish. The urea determinations are the best way of measuring the impairment of the kidney to eliminate solids. The ordinary blood urea test is usually perfectly satisfactory. However, as Dr. Freyberg has said, in cases in which the level of the blood urea is normal there may still be impairment of renal function. The urea clearance test eliminates that diagnostic hazard. The urea clearance test is somewhat impractical, however, because it requires two hours to carry through. The urea ratio, the relationship between the blood urea nitrogen and the nonprotein nitrogen, requires only one specimen of blood and is reliable. I reported the first results on it twenty years ago. I have been using it ever since and have found it to yield satisfactory results.

STUDIES ON CRYSTALLINE VITAMIN B₁

EXPERIMENTAL AND CLINICAL OBSERVATIONS

MARTIN G. VORHAUS, M.D.

ROBERT R. WILLIAMS, M.S.

AND

ROBERT E. WATERMAN, B.S.

NEW YORK

The vast amount of literature that is accumulating on this question of vitamins and their deficiency states has, unfortunately, served to confuse rather than to clarify the clinical aspects of this subject. Very few of the publications available to the profession shed a clear light on the problems involved or offer a satisfactory mode of approach to them.

One of the principal reasons for the prevalent confusion is the growing use of pharmaceutical preparations containing more than one vitamin. The effects attributed to these multiple agents cannot be evaluated accurately. The only hope of ascertaining fundamental data and bringing order out of this chaos is to abandon the use of compound vitamin preparations in experimental clinical work and employ only known quantities of single, pure substances.

Acting on this principle, we have conducted a series of experiments relative to the nature and therapeutic potentialities of the antineuritic vitamin B₁, so designated to indicate its origin in the old vitamin complex known as B. It is safe to assume that our results were due to this single substance, since we employed the pure crystalline material, of known molecular weight and formula.

The normal adult human intake of B₁ is said to be approximately 1 mg daily, the richest sources being the bran coats of grains, leguminous seeds and lean pork. None of the concentrates on the market permit a liberal dosage of this vitamin without the ingestion of considerable amounts of inert or objectionable foreign matter. The pure crystals, which are now available, overcome this objection.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J. June 12, 1935.

Our first report¹ showed the striking increase in the growth rates of rats that received their supply of vitamin B₁ in the form of weighed amounts of the pure crystalline material. It was found that many factors influence the effect of a given amount of this vitamin, so that it is fallacious to speak absolutely of "the B₁ requirement" of a species, whether man or rat. The amount needed is indeterminate unless every component

of the diet is fixed and well defined standards of function are specified. Besides these general considerations there is the factor of individual variation: an individual's requirements may far exceed the normal as a result of abnormalities in digestion and assimilation, impairment of glandular function by an infectious disease, changes resulting from a high carbohydrate intake, or special demands such as those of pregnancy and lactation.

Because true beriberi responds to remarkably small quantities of vitamin B₁, it has been assumed erroneously that a similar situation exists with respect to all B₁ deficiencies. We believe that the minimum therapeutic dose that can be relied on to abolish any accumulated deficit below normal storage capacity and supply current needs is 10 mg daily. Adequate dosage is doubly important in view of the fact that the thera-

peutic response is often the main diagnostic test of the more obscure types of B₁ deficiency. Our first report¹ showed the striking increase in the growth rates of rats that received their supply of vitamin B₁ in the form of weighed amounts of the pure crystalline material. It was found that many factors influence the effect of a given amount of this vitamin, so that it is fallacious to speak absolutely of "the B₁ requirement" of a species, whether man or rat. The amount needed is indeterminate unless every component of 10 mg of this vitamin was administered, orally, daily for four consecutive weeks, to eleven patients with proved diabetes according to present-day standards. Six showed an increased utilization of carbohydrates, five did not. Of the positive cases, two are still maintaining the gain (after five and ten months respectively), two retained the increase for several months, and the remaining two reverted to their previous levels of blood and urinary sugar as soon as administration of the vitamin was stopped. Many factors pointed to a direct causal relationship between the intake of the vitamin and the increased carbohydrate tolerance in 54.6 per cent of the cases, with strong evidence that the action of B₁ in this condition is a catalytic one.

As B₁ is known specifically as the antineuritic vitamin, the third phase of our experiment, presented herewith, consisted of studies of the effects of this substance on a group of patients complaining of nerve pain. These neuritides have been divided, according to accepted clinical classifications, into the types given in table 1.

In table 2 the symptoms of these hundred cases are tabulated and the response to vitamin therapy described. Taking the series as a whole, only 8 per cent failed to react favorably, 44 per cent became entirely symptom free and 48 per cent were definitely improved. These cases have been under observation for periods ranging from three to fourteen months. Up to the present, no recurrence has been noted in any of the forty-four patients in the symptom-free group.

Among the 8 per cent who showed no improvement are several patients with proved organic pathologic conditions to explain their continued symptoms. They were included in this report, however, because their outstanding clinical manifestations were those of either

peutic response is often the main diagnostic test of the more obscure types of B₁ deficiency.

The second stage of our experiment² dealt with the disturbance of the carbohydrate metabolism that has been reported repeatedly in experimental B₁ deficiency. Although a diminished carbohydrate tolerance is encountered in other abnormal states, it is most consistent and marked in B₁ avitaminosis.

The clinical syndrome of diabetes mellitus has many characteristics of a nutritional disturbance the etiology of which is still unknown. Proceeding on the hypothesis that a deficiency of B₁ may be a factor in the production and clinical course of this condition, an average

localized or generalized neuritis and we felt that the presence of definite organic disease was no reason for the rejection of a case. From the beginning, we assumed that the antineuritic vitamin might have a non-specific effect in neuritis, regardless of cause. With this in mind, it seemed of interest to determine whether or not the response of patients without demonstrable basis for the neuritic pain differed from that of patients with known organic disease.

When the cases are classified as to age and sex, it is seen that the number above and below 40 years is virtually the same. Almost three fourths of the patients were females, but allowance must be made for the fact that the series included three pregnancies, as well as eleven anemias of a type having a predilection for women.

It is of interest to note that 75 per cent of the cases demonstrated localized tenderness at one or more points related to pain. Almost invariably this tenderness dis-

appeared as the pain improved. The amelioration of associated symptoms, such as weakness, loss of appetite and paresthesia, far exceeded the relief of pain.

Since many of the acute neuritides subside spontaneously, the duration of symptoms must be considered in interpreting therapeutic results. The preponderant tendency toward chronicity in our cases is therefore noteworthy. In only 15 per cent had the symptoms been

present for less than four weeks, in 50 per cent the duration ranged from one to twelve months, in 35 per cent it was over a year. Twelve per cent of the cases were of more than five years' standing, 23 per cent of one to five years', and 23 per cent of three to twelve months', making a total of 58 per cent in which symptoms had existed for more than three months. This element of time diminishes the probability of spontaneous recovery and appears to confirm the instrumentality of the vitamin therapy.

No claim is made of a "cure" in these cases—any more than it may be said that insulin "cures" diabetes. It is not illogical to assume, however, in an unknown percentage of the patients who were rendered symptom free and have remained so for a long time since the cessation of B₁ therapy that the neuritis may have been due solely to a B₁ deficiency, but this is pure speculation. At the present time there is no way of making such a clinical diagnosis with certainty. The only basis for this theory lies in the clinical response to B₁.

On the other hand, it seems apparent that B₁ has a nonspecific effect in neuritis if the forty-eight cases that were improved but not rendered entirely symptom free are studied. If there had been a B₁ avitaminosis in these patients their symptoms would have disappeared entirely on specific therapy in adequate amounts. Cannot their improvement be ascribed to the action of the vitamin, their failure to become completely well to the continued toxic effects of the original cause?

An analogy may be drawn with the action of iron in the anemias. Just as there is a small group of hypochromic anemias in whom the administration of adequate amounts of iron will result in a complete cure, it is conceivable that there may be a small group of neuritides (usually polyneuritis) in which the ingestion of vitamin B₁ brings about a thoroughly normal state, which is maintained after medication is stopped.

Carrying the analogy further, since the fact is recognized that large doses of iron will improve secondary anemias associated with a large variety of causes such as malnutrition, infection, metabolic diseases and even malignancy, why cannot it be assumed that adequate amounts of B₁ may stimulate reparative processes in the neuraxon, resulting in progress toward the normal state, even in the absence of a B₁ deficiency and regardless of the continued presence of neurotoxins?

An additional series of eight cases, all proved by roentgen examination to be hypotonia of the gastrointestinal tract for which no organic cause could be

demonstrated, was also studied. Three males and five females comprised this group, ranging in age from 19 to 37 years. All complained of marked loss of appetite. There were definite localized or generalized pains in six. In seven, the duration of the constipation was upward of four years, the remaining patient gave a history of alternating diarrhea and constipation for many years.

Since the combination of anorexia and gastrointestinal hypotonia has been observed in experimental animals known to have a B₁ avitaminosis, it was decided to study the effects of B₁ in this group. In all cases, normal appetite returned and the weakness disappeared. Six of the eight experienced a complete restoration of normal bowel function, continuing after medication was stopped. The remaining two showed a marked improvement in elimination, although occasional constipation occurred even during administration of the vitamin. Pain disappeared entirely in five cases and was greatly improved in one.

Reviewing the results in this brief series, it is important to emphasize that these eight patients represent a carefully selected group, in contrast to the neuritic cases, which were accepted at random. We had already observed in the latter that relief of the neuritic pain was not associated with any improvement in the bowel function of those patients suffering from coexisting constipation, so that we had no delusions of dealing with an efficacious constipation remedy. What was sought was a clinical counterpart of the condition of generalized gastro-intestinal hypotonia and marked anorexia that has been observed frequently in experimental animals with B₁ deficiency. The small series

* Roentgen examination in all cases revealed generalized gastrointestinal hypotonia without any demonstrable causes present.

reported herewith presents a similar syndrome. There is no doubt that this type of case represents only a minute fraction of the patients with constipation who are observed clinically.

In view of the large proportion of cases in these studies in which the administration of vitamin B₁ resulted in an amelioration of symptoms, it seems logical to assume that deficiency states are far more frequent than has been thought heretofore. The fact

that most of these cases have not been recognized as such indicates the need for some clinical method of differentiating the various stages of B_1 avitaminosis that will embrace the lesser as well as more intense states. We have attempted to formulate such a concept of vitamin B_1 deficiency in human beings. This is, admittedly, in the formative stage and far from final, but we believe that the time has come, with the material and observations at our disposition, to attempt to define the several clinical phases of B_1 avitaminosis. Recognizing that further research will unquestionably necessitate some revision, we suggest the following tentative basis for continued study.

1 The state of total (?) deficiency of vitamin B_1 that is known clinically as beriberi is well recognized. It is characterized by weakness, pains in the extremities followed by paralysis of the legs, fever, anorexia, diarrhea or constipation, signs of myocardial insufficiency, secondary anemia and, at times, marked edema (dry or wet form). If untreated, it usually results in death, frequently sudden (acute cardiac type).

2 The next most advanced stage, that of severe deficiency of vitamin B_1 , is also recognizable clinically as a state of avitaminosis. Its symptoms are weakness, severe persistent pain in the extremities, paresthesia, anorexia and mild signs of myocardial insufficiency. Sometimes it is associated with edema of the legs and a history of dietary restriction (nutritional edema). In the tropics it is frequently diagnosed as rudimentary beriberi; it may develop into typical beriberi or subside spontaneously.

3 The third stage, continuing in the direction of diminishing severity, is the advanced deficiency of vitamin B_1 , recognized clinically as polyneuritis. Here the principal symptoms are weakness, anorexia and severe pain in one or more of the extremities or elsewhere in the body. This type is sometimes classified as alcoholic polyneuritis or toxic neuritis. It may be associated with bacterial infections, alcoholism, gastrointestinal disease or a deranged carbohydrate metabolism. In some cases it is possible that the deficiency is due less to an insufficient supply of the vitamin than to inadequate absorption.

4 The state of moderate deficiency of vitamin B_1 is usually unrecognized clinically. The symptoms include localized, persistent pain, usually in an extremity or in the back, and anorexia. Paresthesia is frequently present. There is little or no weakness. This condition is usually associated with obesity and a disturbed carbohydrate metabolism. It is frequently classified as diabetic or metabolic neuritis.

5 The least severe stage, mild deficiency of vitamin B_1 , also goes unrecognized. There are vague pains, usually elicited only by pressure over the nerve roots, general malaise, anorexia and constipation. Small amounts of sugar may be present in the urine, without hyperglycemia. There is usually a large carbohydrate intake, often associated with a tendency to obesity. These cases are frequently classified as potential diabetes.

At the present time, as already stated, only the most severe forms of B_1 avitaminosis are wont to receive clinical recognition. In view of the frequent occurrence of lesser degrees of B_1 deficiency, as indicated by an accumulating mass of evidence, a concerted effort should be made to clarify the clinical boundaries that demarcate its various stages. This requires extended research, which will yield reliable results only if known quantities of the pure substance are used in therapeutic

tests. As an aid to further study, the pathologic states in which we believe the administration of vitamin B_1 is indicated are presented.

- 1 Beriberi
- 2 Suspected beriberi
- 3 Polyneuritis
 - (a) Alcoholic.
 - (b) Infectious
 - (c) Toxic.
 - (d) So-called metabolic.
 - (e) Associated with anemia
 - (f) Associated with pregnancy
- 4 Disturbances of the carbohydrate metabolism (including cases now classified as diabetes mellitus)
- 5 Localized neuritis, resistant to usual therapy
- 6 Unexplained anorexia and gastro-intestinal hypotonia

CONCLUSIONS

1 There is evidence to suggest frequent deficiency of vitamin B_1 in the human dietary.

2 At the present time only the state of extreme vitamin B_1 deficiency is usually diagnosed. Lesser degrees of B_1 avitaminosis in human beings rarely receive clinical recognition.

3 Experimental results indicate that amounts of B_1 greater than the quantity necessary to protect against extreme deficiency (i. e., beriberi) produce beneficial effects in lesser deficiencies in both animals and man.

4 Results of a previous study indicate a relationship between vitamin B_1 deficiency and disturbances of the carbohydrate metabolism.

5 In a study of 100 cases of clinical neuritis in which vitamin B_1 was administered orally, forty-four were rendered symptom free, forty-eight were improved and eight showed no benefits.

6 In a group of eight cases of unexplained gastro-intestinal hypotonicity and anorexia, six became free from all symptoms on ingestion of vitamin B_1 , two were improved.

7 The use of a single agent—pure vitamin B_1 —is urged in the study and treatment of suspected B_1 avitaminosis.

145 West Fifty-Eighth Street

ABSTRACT OF DISCUSSION

DR. FREDERICK F. TISDALL, Toronto. So many of us have been accustomed to thinking of a deficiency of vitamin A as showing itself only as xerophthalmia, of B_1 as beriberi, of C as scurvy or of D as rickets, that we frequently lose sight of the fact that a relative deficiency of any one of these vitamins, if carried on over a sufficient length of time, will result in other and just as important signs of ill health. The authors have reported that in 100 cases of nerve pain they obtained improvement and cure by the administration of crystalline vitamin B_1 . How is it that any one could run into such a large number of cases that have formerly not been recognized in which there is a deficiency of this food element? At the Department of Pediatrics of the University of Toronto we took two groups of children in one institution and fed to one group a small amount of a vitamin B_1 and B_2 concentrate and observed their growth. These children were on an excellent diet the same as any one might recommend to one's patients, built up around milk, meat, eggs, vegetables and fruit. The normal children getting the additional B_1 and B_2 grew at a considerably faster rate than those not getting it. This is evidence that children on our present-day excellent diet are not getting an optimal amount of this food element. In view of the fact that in one's diet today from 30 to 40 or even 50 per cent of the calories consumed are supplied by purified food substances, purified flours and sugars that contain no vitamin B_1 , it is obviously deficient in this vitamin. Although vitamin B_1 is widely dis-

tributed in milk, eggs, liver, kidney, vegetables and fruit, it is not abundantly distributed. The work done has shown that in the cooking of vegetables more than 50 per cent of the B_1 vitamin present may be lost. It is not destroyed by heat, but it is destroyed by going into solution in the water that is thrown away. When one stops to consider that the diet is made up of from 30 to 50 per cent of food that contains no vitamin B_1 and from food cooked in water that is thrown away, one can see how the amount of vitamin B_1 necessary for optimal health is not obtained.

DR. MARTIN G. VORHAUS, New York. I want to add one point to the discussion of the frequency of B_1 deficiency. It is one of the few vitamins that the experimental workers in the field believe is not stored in the body, so that, without the normal protection of storage that exists with other vitamins, the probability of a deficiency state is that much more frequent, secondly, experimental workers have shown, and our clinical experience is along the same line, that there is some relation between the degree of carbohydrate intake and the utilization of the vitamin, i. e., the larger the carbohydrate intake, the greater the demand for vitamin B_1 in the human and animal body. Consequently a depletion of B_1 will take place more rapidly on a high carbohydrate diet than it will on a low carbohydrate diet.

DIURETIC ACTION OF POTASSIUM SALTS

NORMAN M. KEITH, MD
AND
MELVIN W. BINGER, MD
ROCHESTER, MINN.

For two centuries certain potassium salts have been employed as diuretics in clinical medicine. In 1679 Thomas Willis¹ recommended the use of potassium nitrate or "salt of niter" in the treatment of dropsy. Wilks and Taylor² used it successfully in 1863. In 1921 Blum³ and Magnus-Levy⁴ were able to show that potassium chloride could be administered safely by mouth in relatively large doses and that it produced frequently a satisfactory diuresis. Since then, McCann and his co-workers,⁵ Osman⁶ and Barker⁷ have obtained similar results with potassium citrate, bicarbonate and chloride. Barker emphasized the importance of giving a diet in which the sodium content was low and that of potassium relatively high. It occurred to us in 1932 that potassium nitrate might be the salt of choice, if potassium itself should have an additional diuretic action to the well known effect of the nitrate radical. We then outlined the present study, which included observations on the relative effect of different potassium salts in both the normal individual and patients having various types of dropsy.

ACTION OF POTASSIUM SALTS ON THE NORMAL INDIVIDUAL

In previous studies⁸ on the action of acid-forming salts our procedure was to give normal individuals a measured amount of a given salt under strict experimental conditions and to compare the urinary output of water and other constituents with that in control periods before and after the ingestion of the salt. The weighed diet was low in water and mineral content, particularly as to chloride and sodium. It was calculated to be sufficient in calories and protein to keep the individual in nitrogen balance. The intake of fluid, in addition to that in the food, was limited to 800 cc daily. The experiment extended over a period of from ten to four teen days, a specific salt being given on five of these days. The potassium salts given were potassium chloride, bicarbonate, nitrate, acetate and citrate. Sodium chloride was given in a single experiment, chiefly to bring out by contrast the relative effects of the potassium and sodium radicals. The salts were administered in 25 per cent solution in a single dose of from 7.5 to 14 Gm. (0.13 to 0.2 Gm. per kilogram of body weight). All five potassium salts produced diuresis with loss of weight (charts 1 and 2).

The sudden decrease in the excretion of water and minerals after discontinuing administration of the salt was a striking finding in each experiment. The nitrate caused a relatively greater diuresis than any of the other salts. The chloride was next in efficiency, and still less efficient were the bicarbonate, acetate and citrate. The nitrate also caused a greater excretion of chloride and sodium than the bicarbonate, acetate and citrate. Potassium was readily excreted after the ingestion of all five salts.⁹ The concentration rose from 0.50 to 0.96 Gm. per hundred cubic centimeters. Thus even with diuresis the normal kidney excreted a urine in which the concentration of potassium reached a figure approximately fifty times greater than that of the blood serum. Such results indicate that potassium concentration by the kidney is similar to that of creatinine, urea and sulphate. It is obviously concentrated in a much greater degree than sodium. The excretion of calcium remained unaltered throughout these experiments. A decrease in ammonia nitrogen, and an increase in the excretion of bicarbonate along with a rise in pH , invariably occurred after the ingestion of potassium bicarbonate, acetate and citrate. These results are similar to those reported with sodium bicarbonate, carbonate and citrate.¹⁰ Changes in the excretion of total nitrogen and inorganic sulphates and phosphates were not uniform and were difficult to interpret. Each twenty-four hour specimen was tested qualitatively for protein, and the result was invariably negative.

The results in subject V (chart 1) after taking sodium chloride are in sharp contrast to those after taking potassium salts. There is an early retention of water, chloride and sodium with a gain in body weight. Later there is an increased excretion of these con-

stituents and a slight fall in weight. These results simply confirm many similar previous experiments with sodium salts.¹¹

In all of our eight experiments with normal individuals (colleagues who kindly consented to undergo the tests), the serum potassium was estimated before the ingestion of the given salt, sometime during its ingestion, and after its administration was discontinued

Chart 1—Normal subjects V, H and O showing daily excretion of water, chloride, sodium and potassium in the urine and the concentration of potassium in the serum after they had ingested sodium chloride, potassium chloride and potassium bicarbonate.

The sample of serum was withdrawn in the morning at the end of the twenty-four hour period. No change was observed in the serum of subject V, who received sodium chloride. This constituted a control for the seven individuals who were given potassium salts. In the latter, the potassium of the serum either rose a few milligrams or, as in M (chart 2), T and H (chart 1), increased distinctly to 33, 37 and 40 mg per hundred cubic centimeters, or 84, 95, 102 milliequivalents, respectively.¹² No toxic symptoms were noted in any of the seven individuals. Thus, in seven normal subjects under the same experimental conditions, including diet and intake of fluid, the potassium was readily absorbed and excreted, yet the concentration of the serum varied only from 20 to 40 mg per hundred cubic centimeters (51 to 102 milliequivalents). Further study is necessary to explain these variations in the concentration of the serum.

In order to study the initial effects produced by administration of potassium salts, two short experiments, nine hours in duration, were carried out with two normal individuals, K and B (chart 3). No food was taken for twelve hours preceding or during the experiment, however, 600 cc of water was ingested during the experiment. A control specimen of urine was collected from 7 to 8 a. m. At 8 a. m., 125 Gm of potassium acetate or nitrate was ingested and specimens of urine were collected at 8 15, 8 30, and 9 o'clock, and subsequently at hourly intervals for the next seven hours. Specimens of venous blood were

withdrawn frequently during the experiment. After potassium acetate was taken by subject K there was an increase in the renal excretion of water, chloride, carbonate and potassium, the p_H of the urine rose from 5.9 to 8.3. The changes in the blood were a small increase in the carbon dioxide capacity of the plasma, from 62 to 69 volumes per cent, and a slight rise in the serum concentration of potassium, from 18 to 20 mg per hundred cubic centimeters, 46 to 51 milliequivalents. The concentration of potassium in the urine rose to 0.95 Gm per hundred cubic centimeters, or fifty times that of the serum. After deducting the probable excretion of potassium by a starving individual, estimated from the excretion on the first day of a prolonged fast by Benedict's subject,¹³ this individual excreted 49 per cent of that ingested in eight hours.

The experiment with subject B was similar in every detail to that with K with the single exception that the same amount of potassium nitrate was ingested instead of potassium acetate. The results were in many respects similar, although there was a relatively greater diuresis and a greater excretion of chloride and potassium than in the previous experiment. The p_H did rise, but it fluctuated quite markedly from specimen to specimen. The changes in the blood were (1) a slight decrease in the carbon dioxide capacity of the plasma, from 66 to 55 volumes per cent, and (2) a small rise in the concentration of potassium in the serum from 18 to 23 mg per hundred cubic centimeters (46 to 59 milliequivalents). The maximal concentration of potassium in the urine was 0.76 Gm per hundred cubic centimeters, or forty-two times that of the serum. This is a slightly lower figure than in the previous experiment and is probably to be accounted for by the greater

Chart 2—Normal subjects G, M and W showing daily excretion of water, chloride, sodium and potassium in the urine and the concentration of potassium in the serum after they had ingested potassium nitrate, potassium acetate and potassium citrate.

increase in the volume of urine. The calculated percentage excretion of potassium ingested was 64. A routine qualitative test for protein was made in each specimen of urine in these two experiments, and no protein was demonstrated.

These two short experiments indicate that potassium salts are promptly absorbed and readily excreted and that the changes in blood and urine are very similar to those obtained in the previous experiments extending over a period of several days

ACTION OF POTASSIUM SALTS ON PATIENTS WITH EDEMA

During the last three years we have administered potassium salts to sixty patients with edema. Twenty-nine patients had chronic nephritis with edema, twenty had myocardial degeneration with decompensation, seven had cirrhosis of the liver with ascites and edema, one had polyserositis with tuberculosis of the peritoneum, and in three cases there was edema of indeterminate origin. The diuretic results were very satisfactory in twenty-nine cases (48 per cent), fair in twenty (33 per cent), and a failure in eleven (18 per cent). An increased urinary output was thus observed in 80 per cent of the cases. In four cases

sweat obviously could not account for this marked discrepancy between intake and urinary output. This result suggested replacement of sodium by potassium in the tissues. Throughout diuresis the daily excretion of protein in the urine was from 1.5 to 5.2 Gm per hundred cubic centimeters.¹⁴ At the time the patient was free from edema, the analysis of the chemical constituents of the blood indicated a slight reduction in the plasma alkali reserve, but otherwise there was an improvement in renal function. In spite of a retention of potassium the rise in serum concentration was slight.

CASE 2 (subject G, chart 4)—A woman, aged 24, gave a history of albuminuria for one year and of general edema for six months. On examination there was no gross anemia, but there was slight puffiness of the eyelids and moderate edema of the lower part of the back and legs. The blood pressure in millimeters of mercury was 105 systolic and 75 diastolic, and the ocular fundi appeared normal. Routine urinalyses revealed a heavy precipitation of albumin, a few hyaline casts and a few leukocytes, but no erythrocytes. Values for certain constituents of the blood are given in the table. A diagnosis of chronic glomerulonephritis with features of chronic lipid nephrosis was made.

Results of Examination of the Blood of Various Subjects

quantitative studies similar to those just described for normal subjects were carried out

CASE 1 (subject A, chart 4)—A youth, aged 19 years, who had had albuminuria and edema for five weeks, was given potassium chloride. Preliminary examination showed that he had a moderate degree of general edema, some anemia, with a hemoglobin concentration of 11.1 Gm per hundred cubic centimeters, and erythrocytes numbering 3,560,000 per cubic millimeter. The urinary changes were characteristic of sub-acute glomerulonephritis and there were definite renal functional disturbances. The blood pressure was usually normal and the ocular fundi showed no abnormalities. The values for certain constituents of the blood are given in the accompanying table.

Following the exhibition of a weighed diet consisting of from 1,600 to 2,500 calories, 40 to 50 Gm of protein, a low mineral and water content, 600 cc of extra fluid, and 105 Gm of potassium chloride in thirteen days, the edema disappeared and the patient's weight decreased 24 pounds (11 Kg). Diuresis was indicated by a rise in the daily volume of urine from 600 to 1,480 cc. There was an increased excretion of chloride, sodium and potassium. The potassium concentration rose to 0.41 per cent, seventeen times the concentration in the serum. The total output of sodium was relatively much greater than that of potassium. The comparatively small urinary output of potassium indicated that potassium was retained in considerable quantity. The amount of potassium excreted in the stools and

Treatment consisted of a weighed diet of 2,500 calories, 77 Gm of protein, a low mineral and water content and 600 cc. of extra fluid, and potassium nitrate, 12 Gm. (0.2 Gm. per kilogram of body weight) daily. Mild diuresis followed, with a loss of weight of 15 pounds (6.8 Kg) in five days. The patient was now free from visible edema. The diuresis was accompanied by a considerable increase in the excretion of potassium, chloride and nitrate, but by a relatively small increase in sodium. The concentration of potassium rose to 0.95 Gm. per hundred cubic centimeters, or fifty times that of the serum. These results in regard to the relative amounts of sodium and potassium excreted are somewhat the reverse of the results in case 1 (subject A). The excretion of calcium was extremely small. The daily output of protein was considerable, varying from 5.2 to 8.2 Gm. Both in this and in the previous case the presence of a considerable amount of protein in the urine did not seem to hinder the diuretic response, nor was the function of the kidney further impaired. At the termination of diuresis the changes in the blood were a slight retention of nitrate, without retention of potassium or a notable shift in the alkali reserve.

CASE 3 (subject S in the table)—A married woman, aged 35, complained chiefly that for six months she had had edema of the feet, legs and face. On physical examination there was no

14 The protein in the urine was determined by subtracting the non-protein nitrogen from the total nitrogen and by multiplying the result by 6.25. The nonprotein nitrogen was estimated after precipitating the protein with Folin's tungstic acid reagent.

demonstrable anemia. The blood pressure was 100 systolic and 60 diastolic. There was definite edema of the feet, legs and lumbosacral region, reaching as high as the eighth thoracic vertebra. Further studies showed that there were no abnormal constituents in the urine, which included examination for lipid bodies. The basal metabolic rate was +2. The serologic test for syphilis was negative. All tests of renal function gave normal readings. However, the concentration of serum protein was very greatly reduced, to 27 Gm, the albumin content to 14 Gm and the calcium content to 65 Mg per hundred cubic centimeters, as shown in the table. Edema fluid obtained through a needle inserted in the leg was water clear and contained only 0.1 per cent of protein. A diagnosis of an indeterminate type of edema associated with hypoproteinemia was made.

Treatment consisted of a weighed diet of approximately 2,000 calories, from 80 to 100 Gm of protein, and a low mineral and water content. Extra fluid was limited to 800 cc. Nine grams of potassium nitrate was administered daily for fourteen days and, because of the low serum calcium from the fifth to the fourteenth day, 12 Gm of calcium lactate was also given daily. On this regimen diuresis developed, the volume of urine varying from 900 to 2,080 cc. There was an increased excretion of chloride, nitrate, sodium and potassium. The concentration of potassium increased to 0.41 Gm per hundred cubic centimeters, seventeen times that of the serum. A slight increase in calcium output occurred. No demonstrable amount of protein was excreted during this experimental period. When the patient became edema free, she had lost 14 pounds (6.4 Kg).

The noticeable changes in the blood were the considerable rise in serum protein and albumin and calcium contents. During diuresis the serum potassium rose to 24 mg per hundred cubic centimeters (6.2 milliequivalents), but it fell to 18 mg (4.6 milliequivalents) at the termination of the diuresis. Similarly, the plasma nitrate rose to 0.7 mg per hundred cubic centimeters during diuresis.

CASE 4 (subject Pe., chart 5)—A man, aged 58, a city clerk, had always been a heavy drinker of alcohol, and five months before admission the abdomen had become swollen. During the last four months abdominal paracentesis was performed on five occasions, several liters of fluid being drained at each operation. The patient's ankles had been swollen for three

25 mg per hundred cubic centimeters (direct reaction). A provisional diagnosis of hepatic insufficiency, cirrhosis (?) ascites and left pleural effusion was made. The etiology of the patient's disease remained obscure. Treatment consisted of paracentesis of the left pleural cavity on three occasions and of the abdominal cavity twice. Fluid in the amount of 12,500 cc was removed in this manner. After paracentesis a firm edge presumably of the liver, was palpated 6 cm below the right costal margin.

The results of examination of the blood are given in the table.

For a period of twelve days the patient was given a weighed diet consisting of from 1,335 to 2,350 calories, 35 to 49 Gm of protein, and a low intake of minerals and water. Extra fluid was limited to 800 cc. The patient also ingested potassium chloride, 5 Gm daily. On this regimen there was a loss in weight of 2 Kg, probably due to withdrawal of 1,000 cc. from the left part of the chest and 2,500 cc from the peritoneal cavity, a decrease in the dependent edema and at times a slight increase in the volume of urine but no actual and steady diuresis. The excretion of chloride and potassium was increased, the concentration of the latter rising to 0.6 Gm per hundred cubic centimeters. The excretion of sodium was very small and was uniform throughout. On the seventh day the serum potassium rose to 37 mg per hundred cubic centimeters (9.1 milliequivalents), but later fell to the initial figure of 20 mg (5.1 milliequivalents). In this case there occurred a distinct retention of potassium and a slight decrease in the alkali reserve, even though the dose of potassium chloride was small.

Two further cases are of interest because of the excellent diuretic response obtained. Detailed chemical analyses of the urine were not made as in the previous four cases.

CASE 5 (subject Pw in the table)—A farmer, aged 39, when admitted to the clinic stated that his illness had begun eight months previously with general edema and albuminuria. A diagnosis of chronic glomerulonephritis with edema was made.

CASE 6 (subject B., chart 6)—The patient was a rancher, aged 56. A diagnosis of myxedema, myocardial degeneration with decompensation and renal insufficiency was made.

DOSE OF POTASSIUM SALTS

The amount of a given salt administered in order to produce diuresis is considerably greater than the dose given in the United States and British pharmacopoeias. Taking 12.5 Gm of potassium nitrate as a useful standard daily dose, we gave to normal individuals, for comparative purposes, approximately its atomic equivalent of the other potassium salts. The content of potassium was about 5 Gm. This amount has been the usual maximal dose given to patients with edema. However, subject H was given 24.5 Gm of potassium salts, 12 Gm of nitrate, and 12.5 Gm of the bicarbonate, daily, for a period of thirteen days. The

Chart 3—Normal subjects K and B showing hourly excretion of water, chloride, sodium (B) and potassium in the urine and the concentration of potassium in the serum after they had ingested potassium acetate and potassium nitrate.

months. On examination there was evidence of fluid in the left pleural cavity, marked ascites was present, and there was moderate edema of the lumbosacral region and of the legs. There were no definite evidences of myocardial insufficiency. Secondary anemia was slight. Routine urinalyses and tests of renal function were essentially normal. The serologic test for syphilis was negative. The dye test of hepatic function revealed marked retention in the blood, and the serum bilirubin was

potassium content amounted to 9.5 Gm daily. No ill effects were observed. Similar maximal daily doses of the chloride, nitrate, bicarbonate, acetate and citrate have been successfully employed previously by Blum,³ Wilks and Taylor,² Nonnenbruch,¹⁵ Fleckseder,¹⁶ and Basset, Elden and McCann.⁵ Their doses varied from 16.5 to 30 Gm of the salt and from 6.6 to 13 Gm of potassium.

Caution must be used in administering these large doses, and all are agreed that smaller trial doses should

Chart 5—Subject Pe, showing daily excretion of water, chloride, sodium, potassium and total nitrogen in the urine after ingestion of potassium chloride. Para centesis of left pleura at P and of peritoneal cavity at A.

effect is similar to that of the acid-producing salts and organic mercury and these salts and caffeine compounds.

TOXIC ACTION

Potassium salts, when injected intravenously into animals, can cause rapid toxic effects, particularly on the heart. The experiments of Blake,¹⁷ Grandeau¹⁸ and Traube¹⁹ carried out years ago are often quoted to emphasize this fact. Mathison²⁰ in 1911 was able to show that potassium chloride, when injected into the central portion of the carotid artery of the cat, not only was less toxic but actually caused a rise in blood pressure in contrast to a fall after intravenous injection. He attributed the toxic action after intravenous injection to the high concentration of potassium, which almost at once reaches the heart muscle. Amberg and Helmholz²¹ in 1916 determined the toxicity of intravenously injected potassium chloride and sulphate in the guinea-pig. They found that the lethal dose was

very small, from 10 to 17.5 mg per hundred grams of body weight, when the solutions, 1 per cent potassium chloride and 1.75 per cent sulphate, were injected at the rate of 1 cc per minute. A much larger dose was necessary to kill the animal if it had received a previous injection of sodium chloride. In 1925 Whelan,²² studying some biochemical effects of intravenously injected chlorides in dogs, noted that seven animals, when given 0.1 Gm of potassium chloride per kilogram of body weight, in ten minutes showed no obvious toxic effects. Such results seem to show that slowing the rate of injection is an important factor in protecting the heart from too concentrated a solution of the potassium salt. Two experiments reported by Nicholson and Soffer²³ early this year also support the view that slow intravenous injections can be much better tolerated than rapid ones.

What is the concentration of potassium in the blood serum that is toxic to the heart? McLean, Bay and Hastings²⁴ have recently carried out a series of perfusion experiments on the isolated heart of the rabbit and found that when the concentration of potassium in the perfusion fluid was increased to 48 mg per hundred cubic centimeters (120 milliequivalents per liter) ventricular fibrillation and minimal ventricular contractions were observed. These results support Cushny's statement²⁵ that a concentration of potassium in the serum of greater than about 50 mg per hundred cubic centimeters (128 milliequivalents) is highly poisonous to the heart. The highest concentration of potassium in the serum of our normal controls and of patients when taking potassium salts has been 40 mg per hundred cubic centimeters (102 milliequivalents), or well under this figure. Rabinowitch,²⁶ however, reported serum concentration of 58 and 72 mg per hundred cubic centimeters (149 and 185 milliequivalents) in two cases, one of eclampsia and the other of uremia, but he does not mention any outspoken and noticeably toxic effect on the heart. Magnus-Levy⁴ and others have stressed

Chart 6—Subject B showing daily volume of urine and changes in blood urea and body weight after ingestion of potassium nitrate.

that toxic effects produced during a perfusion experiment may not necessarily occur in the intact animal.

We believe that the results of experimental studies on animals contraindicate, at present at least, the intravenous administration of any considerable amount of

potassium salts in clinical medicine. On the other hand we have shown that normal individuals can take a large dose of a potassium salt by mouth without demonstrable toxic effects. Many observers have given really enormous doses of potassium salts for a considerable period to patients with edema and no untoward effects have occurred. In our present series subject H, previously mentioned, took by mouth 871 Gm of potassium salts (358 Gm of potassium) in a period of sixty-eight days. The patient during this entire period took the diet and potassium salts regularly, the salts including potassium nitrate, chloride and bicarbonate. There were no complaints and no definite toxic symptoms. These large doses of potassium salts failed to establish satisfactory diuresis but produced a condition favorable for the accumulation of potassium in the body. However, the rise of potassium in the serum was very small, 26 mg per hundred cubic centimeters (6.6 milliequivalents), on the thirty-ninth day, and 24 mg (6.2 milliequivalents), on the sixty-eighth day.

Even the aforementioned large doses of potassium by mouth are often exceeded by normal individuals whose diet includes large quantities of food rich in potassium. Bunge²⁷ stated that certain Irish laborers eating chiefly potatoes and certain African tribes living on native foods may ingest as much as 50 Gm of potassium daily without toxic symptoms. The daily ration of our hospital diets contains from 3 to 5 Gm of potassium. The comparative safety with which one can administer food containing potassium and potassium salts by mouth is probably due to several factors, the most important being the rate of absorption from the intestine into the portal system, the dilution or detoxification of the salts in the blood stream or during their passage through the liver, and their rapid excretion by the kidney.

Magnus-Levy,⁴ Blum⁵ and Smellie²⁸ reported toxic effects in a few patients with cardiac decompensation and edema but no fatalities. Estimations of potassium in serum or urine were not made. We have found it difficult in the written descriptions of these few cases to eliminate entirely the possibility of independent accidents, such as coronary occlusion and acute myocardial failure, so that it is not possible to ascribe the symptoms definitely to potassium intoxication. Pilcher, Calhoun, Cullen and Harrison²⁹ have also shown that the potassium content of skeletal muscle is decreased in congestive heart failure and have administered potassium dibasic phosphate (up to 14 Gm daily) in such cases. In order to avoid any toxic effects, Blum⁵ and Magnus-Levy⁴ advise giving small, initial trial doses in this type of cardiac case, and this is undoubtedly a wise procedure. Up to the present we have never given potassium salts to a patient with extreme oliguria or anuria, or to one whose blood urea was greater than 100 mg per hundred cubic centimeters. In case 6 (subject B) a urea content of 100 mg per hundred cubic centimeters did not prevent satisfactory diuretic action. Small initial doses, advocated in cardiac cases, would also seem to be indicated in cases of dropsy with severe renal insufficiency. Bolliger and Breh³⁰ demonstrated

that in experimental chronic renal insufficiency in the dog the potassium concentration of the blood serum invariably rises. On the other hand, Rabinowitch³¹ found a remarkable variation in the concentration of potassium in the serum of patients in severe uremia. In one such case the concentration rose to 72 mg per hundred cubic centimeters (18.5 milliequivalents), but in several other cases with just as severe retention of urea and creatinine in the blood the values were normal. The distribution of potassium in the tissues of uremic patients would therefore appear to be regulated by factors other than simply a reduced permeability of the kidneys for potassium.

In the experiments of Amberg and Helmholtz just mentioned, a preliminary injection of sodium chloride made it necessary to increase the lethal dose of a potassium salt. Osman,⁶ in giving large amounts of alkalis to patients with edema, combined potassium and sodium salts in order to protect the patient against the possible toxic effects of potassium. These facts bring up the question as to whether the actual amount of sodium in the body is a determining factor in potassium poisoning. In adrenal insufficiency the amount of sodium is reduced both in the blood serum and in the tissues, while there is often an increase in the concentration of potassium in the serum. Potassium poisoning, therefore, has been suggested as a cause of the serious symptoms. No such toxic symptoms or relationship have been observed in the present study. The concentration of sodium in the serum varied from 285 to 374 mg per hundred cubic centimeters without any demonstrable relation to the potassium content. Rabinowitch's observations on uremic blood did not show any definite relationship between the sodium and the potassium content. Further experimental work in actual potassium toxemia is necessary to determine the relative significance of the potassium, the sodium and possibly the calcium content of the blood serum.

In any discussion of toxicity of potassium salts the action of the specific anion must be considered. One of us³¹ has described the possible toxic effects of the nitrate radical and how these can usually be prevented. The chloride ion has a stronger tendency than the nitrate ion to cause a shift in the acid-base equilibrium to the acid side. Undoubtedly the acid producing salts ammonium chloride and ammonium nitrate have produced an acidosis, with further reduction of renal function in certain types of renal disease.³² Potassium, bicarbonate, acetate and citrate cause an increased renal excretion of carbonate with a decided shift of the urinary p_H to the alkaline side, and we have not seen any definite harmful action from these effects. This observation agrees with previous clinical experience that potassium bicarbonate, citrate and acetate can be given safely in comparatively large doses.

COMMENT

These biochemical studies indicate that potassium is readily absorbed from the intestine, disappears quickly into the tissues, and can be rapidly excreted by the kidney. The small amount in the blood serum, even after ingestion of a considerable quantity, raises the question as to its manner of storage and subsequent liberation for excretion. The two chief storehouses of potassium are the erythrocytes of the blood stream and the cells of voluntary muscle. In health, any excess

seems to be quickly removed from the blood serum and is then gradually excreted by the kidneys. Following depletion of potassium due to starvation and that seen in cardiac edema, there is retention with a refilling of the muscle storehouse. Was the potassium retention in case 1 (subject A) with anemia due to an analogous need for the refilling of the potassium storehouse in the erythrocytes? The efficiency with which the kidney concentrates potassium, at least fifty times, readily explains the rapid elimination of a great excess taken in the diet by eaters of potatoes, for example. The sustained high concentration in the urine in case 2 (subject G), in which there was a definite renal lesion, suggests that the ability of the kidney to excrete potassium may be maintained late in chronic nephritis in a similar way to its ability to eliminate creatinine. The much greater concentration by the kidneys of potassium than sodium may possibly be explained by less reabsorption of the former in the renal tubules.

Bunge²⁷ suggested that potassium and sodium may replace each other in the animal organism. The experimental evidence he gave was that the ingestion of potassium salts resulted in a definitely increased excretion of sodium in the urine. Our data reveal an increased excretion of sodium by some of our normal individuals and in case 1 (subject A), in the normal individual M and in cases 2 and 4 (subjects G and Pe respectively), however, the increase was insignificant. These results together with those of Miller³³ again emphasize the well known fact that potassium and sodium have certain independent biologic functions, as, for instance, the high concentration of sodium in blood serum and interstitial fluid in contrast to the small content of potassium, the high concentration of potassium in the erythrocytes with little or no sodium present, and also the initial retention of water with the ingestion of sodium salts in contrast to loss of water after taking potassium salts.

In the present study five potassium salts have been shown to cause diuresis. The cation potassium is readily excreted in each instance by the kidney, it also brings about a definite shift of the acid-base equilibrium in the urine toward the alkaline side. These two facts offer a possible explanation for its diuretic action. It should be pointed out, however, that of the five salts the nitrate produced the most marked effect, which emphasizes the importance of the anion as well as the cation in considering the diuretic action of a given salt.

Our clinical results with potassium salts have been encouraging. They confirm the results of the therapeutists of the last eighty years³⁵. We prefer potassium nitrate because, after its use, diuresis frequently occurs. In our experience it is less likely to cause toxic symptoms than ammonium nitrate. Its action, when combined with other diuretics, is also often satisfactory. Diuresis from potassium nitrate may be initiated more slowly and be of longer duration than that of other diuretics, but it is less likely to cause untoward effects. Organic compounds of mercury act more rapidly but in so doing may injure tissues, such as those of a diseased kidney. Potassium salts, more particularly the bicarbonate, acetate and citrate, produce a rapid shift in the acid-base balance, rendering the plasma and urine more alkaline. This action sug-

gests that these potassium salts may be more effective and less likely to cause edema in combating acidosis than sodium salts. They might also be used when a strongly alkaline urine is desired.

ABSTRACT OF DISCUSSION

DR HERBERT BARKER, Chicago. Drs Keith and Binger's paper brings out two points that are of special interest to me: that the potassium salts may be used in a variety of conditions for their diuretic effect and that they may be used in those conditions without fear of toxicity. Their report should aid in dispelling fears in connection with the administration of potassium to patients with renal disease. Five years' use of potassium chloride has not given any untoward effects except in possibly three instances. All three patients were suffering from advanced glomerular nephritis with edema, hypertension and nitrogen retention, so that there were many factors entering into the symptomatology. The symptoms in question were those of weakness and increased feeble heart action with a gallop rhythm. The blood potassiums at that time were 35, 35 and 40 mg per hundred cubic centimeters. These are the highest blood potassium readings I have obtained with doses ranging from 3 to 10 Gm daily. Doses as great as 60 Gm daily have been reported in the literature and the only untoward effects recorded are nausea, vomiting and diarrhea. I have had no experience with potassium nitrate. Chemically it should be effective when the acid base equilibrium is not greatly disturbed. My experience with potassium chloride has been largely confined to the chronic cardiac edemas of valvular and hypertensive vascular types. In these cases the reduction of chlorides in the body due to long standing salt restriction renders a diuresis very poor with diuretics, especially the mercurials. It is therefore especially important to administer chlorides, as the potassium or ammonium salts, until blood chlorides are raised to 500 mg or more per hundred cubic centimeters. I feel, therefore, that the mineral control of fluid balance, though relatively simple to operate, is often much more effective when blood chemical determinations are used to assist in choosing the proper salt for administration, and it is equally important as a guide to probable desirable changes from one salt to another as the course of the disorder progresses.

DR CARL H. GREENE, New York. A great deal of credit is due to the men who pointed out the relationship between water retention and salt metabolism in the body and demonstrated the clinical application of these facts in the management of cases of renal disease. When ammonium chloride and calcium chloride were first introduced it was believed that diuresis was due to the acidifying action of the chloride ion. When ammonium nitrate was introduced it was suggested that the nitrate ion perhaps had a specific diuretic action of its own. The diuretic action of potassium chloride, on the other hand, has been explained in part at least as the displacement of sodium salts in the body by potassium salts. I hope that the authors will tell us a little more with regard to their conclusions as to the relative importance of these various effects in determining the diuretic action of potassium nitrate. The administration of ammonium salts must be carried out with care to avoid unpleasant gastro-intestinal symptoms. How do the authors administer potassium nitrate and in what medium or vehicle? Do they consider that there are specific indications which would lead them to use potassium nitrate in a case instead of the other acid salts with which the profession is more familiar?

DR MELVIN W. BINGER, Rochester, Minn. Dr Greene has asked a difficult question regarding the point of action of potassium salts. I feel that there is certain displacement of sodium in the blood and in the tissues by potassium, but I do not feel that this is the total action of potassium as a diuretic. The red blood cells contain a larger percentage of potassium than the plasma. The plasma contains more sodium, and it is not known whether there is a shift in this balance in the administration of potassium salts. I rather feel that there is some shift in electrolytic ionization, although there may be a direct action on the kidney itself. Regarding the administration of potassium nitrate, we are using enteric-coated pills of 0.5 Gm., and we

give from sixteen to twenty-four of these daily Potassium nitrate can be given in a 12 per cent solution, two tablespoonfuls three or four times a day, but it does upset the stomach and, if given on an empty stomach in a 12 or 25 per cent solution, it will cause irritation. In fact, the morning that I took 125 Gm (25 per cent solution) I developed severe abdominal cramps, which lasted about half an hour. Of course, it was on an empty stomach and double the concentration that is usually given. We advise patients to take potassium nitrate after their meals. They are put on a salt-free, low-fluid (from 800 to 1,000 cc) diet and usually 50 Gm of protein daily unless the serum protein is low, as in the nephrosis type of case. In such cases the protein intake is increased to 75 or 100 Gm daily.

PRIMARY ESOPHAGEAL CARCINOMA, WITH ESPECIAL REFERENCE TO A NONSTENOSING VARIETY

A CLINICOPATHOLOGIC STUDY BASED ON ONE
HUNDRED AND EIGHT NECROPSIES

ROBERT W. MATHEWS, MD

AND

TRUMAN G. SCHNABEL, MD

PHILADELPHIA

Recently, within a comparatively short period, autopsies revealed esophageal carcinoma in four patients who had not presented dysphagia, pain, regurgitation of food and vomiting, the characteristic symptoms. In the absence of the usual clinical picture presented by the disease, their physicians had not appreciated the presence of a new growth in the esophagus; they found some consolation for their failure in diagnosis, however, in the fact that the postmortem examination presented carcinomatous lesions which were nonstenosing and therefore did not obstruct the passage of food.

The evidence in these four cases prompted the undertaking of a clinicopathologic analysis of the Philadelphia General Hospital series of patients from 1920 to 1933. It was hoped that such a study might point the way to certain conclusions concerning the incidence of nonobstructive carcinomatous lesions in the esophagus, that distinguishing clinical evidences might be brought to light, that the relative degree of clinical and pathologic malignancy of stenosing and nonstenosing tumors might be illuminated, and that perhaps other important changes concerning both the obstructive and the non-obstructive variety might be revealed.

MATERIAL

During the thirteen year period approximately 260,000 patients were admitted to this institution. Of this number, 247 had carcinoma of the esophagus, making an admission rate of slightly less than 0.1 per cent. Two hundred and twenty-six of this group died in the hospital and the remainder died after being discharged. One hundred and eight came to autopsy, of this number twenty-two, or 20.3 per cent, exhibited a nonstenosing variety of lesion, and in eighty-six the lesion was certainly obstructive. The results of the clinicopathologic study of these autopsies are presented herewith.

SEX

The general admission records of this hospital show that 56 per cent are females. The general autopsy

record shows that 40 per cent are females. In this especial group of 247 patients presenting esophageal carcinoma, including both the 108 cases that came to autopsy and the 139 cases in which an autopsy was not done, 73 per cent were women. Among the number with obstructive tumors 58 per cent were women, and among the number with the nonobstructive variety of the disease 13.6 per cent were women.

AGE AND RACE

A majority of the patients were between 50 and 70 years of age. Among those with stenosing carcinoma 67 per cent were within this age range, and among those with the nonstenosing form 68 per cent were within the same range. In the first group the youngest patient was 42 and the oldest 85, while in the latter group the youngest was 35 and the oldest was 91.

There were eighty-four white (77.7 per cent), twenty-two Negro (20.3 per cent), and two Chinese (1.9 per cent) patients in the autopsy series of 108. Both the admission and the autopsy records show that 33.3 per cent were Negroes. In the entire series of 247, the percentage of Negroes was 11.5.

HISTORICAL DATA

The historical data obtained from these patients were much alike as to both the obstructive and the non-obstructive type. In the combined group the history of five patients showed familial cancer, and in the history of two patients there was a vague suggestion of it. The

TABLE 1—Incidence

| Sex | Stenosing | Nonstenosing |

| Males | 61 | 15 |
| Females | 5 | 3 |

father of one patient had died of carcinoma of the esophagus. The histories as to previous illnesses, occupations and habits of life were so varied that they did not warrant definite conclusions. The fact that the group history was singularly free from evidence of alcoholism may be the more in point because the patients

TABLE 2—Metastases

| | Stenosing | Nonstenosing |

| Number of cases | 80 | 22 |
| Regional nodes | 60 | 21 |
| Abdominal nodes | 34 | 10 |
| Lungs | 16 | 4 |
| Liver | 21 | 0 |

represented, generally speaking, a low economic and cultural level. It has been suggested, indeed, that hardship may be a predisposing factor in the development of cancer of the esophagus. Five of the autopsy group had positive Wassermann reactions and a few had pulmonary tuberculosis.

PATHOLOGIC CHANGES

The three gross anatomic types of esophageal carcinoma found at postmortem examination were:

First, a large fungating carcinoma which protruded into the lumen, producing obstruction with dilatation proximal to the new growth. This type was responsible for the well known clinical syndrome of obstruction.

Second, an annular type, often partially or completely surrounding the lumen of the esophagus, extending out-

ward and adhering to adjacent structures but not encroaching on the lumen. This type was ordinarily nonstenosing but produced dysphagia in some instances by reason of the esophagus being anchored (as often occurs in this type) at an unusual point or points. The mucosa often appeared grossly to be intact.

Chart 1—Age incidence in stenosing and nonstenosing tumors

Third, the ulcerating type, with no narrowing of the lumen, usually with dilatation of the esophagus. This variety was always nonstenosing.

Fifty-one per cent of the new growths were located in the middle third of the esophagus. In this autopsy series there were no nonstenosing lesions found in the upper third. Eighty per cent of the stenotic tumors were found in the lower two thirds while all the nonstenosing variety were discovered there.

Histologic study showed all the tumors to be of either squamous or undifferentiated types of carcinoma. Some patients in the records were diagnosed as having cancer of the esophagus, but further study of the stained sections and the description of gross lesions

record, diagnosed grossly and microscopically as having primary cancer of the esophagus, ten slides were not available to this analysis for graded study.

According to Broders' classification, approximately 52.5 per cent of the stenosing and nonstenosing tumors revealed grade 2 carcinoma structure, 40.7 per cent of the stenosing group were grades 3 and 4, while 47 per cent of the nonstenosing group showed cells of the same grades.

The average prehospital duration of symptoms for the patients of the stenosing type was 193 days. The average of their hospital stay was forty-one days. For the nonstenosing type, the average symptom time was seventy-five days and the average hospital stay thirteen days. One patient with nonobstructing carcinoma had had symptoms for two years, while another had complained for only two days before admission to the hospital.

Chart 5 shows that the patients having grade 2 stenosing tumors complained of their symptoms on an average of 225 days before death. The shortest period of illness, 180 days, occurred in the grade 3 class of stenosing tumors. This apparently indicates an approximate difference of only a month and a half. Undifferentiated nonstenosing grades of tumors were characterized by an average duration of symptoms of

Chart 3—Location of pain in cases of stenosing and nonstenosing tumors

116 days and grade 3 by a duration of about seventy-five days, showing also an approximate difference of a month and a half.

Table 2 indicates the sites to which the primary esophageal lesion most frequently metastasized. The location and degree of metastasis did not seem to vary perceptibly as between the stenosing and nonstenosing types. Occasional metastases were found in the stomach, pancreas, kidneys, adrenals, diaphragm, pleurae, pericardium, spleen, thyroid, trachea and aorta. From the histopathologic point of view, all the various types of carcinoma showed a tendency toward infiltration, permeation and/or metastasis, and no relation was noted between the grade found and the degree of extension.

CLINICAL FEATURES

Dysphagia was the earliest and most frequent complaint among the eighty-six patients with stenosing tumors. It was recorded in 94 per cent of such cases. In the nonobstructive group of twenty-two, three complained of dysphagia. In one of these three the esophagus was found to be adherent to the aorta. In another a mediastinal abscess was found. In the third there was an extensive permeation of the posterior mediastinum. Weight loss ranging from a few to a hundred pounds or more occurred in about 75 per cent of the patients, in both the obstructive and the nonobstructive

Chart 2—Race incidence in stenosing and nonstenosing tumors

showed very clearly that they were examples of adenocarcinoma involving the cardia and represented secondary extension to the esophagus from primary cancer of the stomach. Such patients have not been included in this study, contrary to the habit of some writers who have presented analytic reports on carcinoma of the esophagus, based at times on tissue secured through the esophagoscope for biopsy. Of the patients on original

group While pain was complained of in both groups, it was noted in 60 per cent of the nonstenosing tumors as against only 39 per cent of the stenosing The pain varied greatly in character and location, sometimes it was complained of in more than one region It might be by turns dull, sharp, boring or burning, in some

Chart 4—Cell grade (Broders) of stenosing and nonstenosing tumors Undif indicates undifferentiated grade consisting of small, round cells impossible to classify except as carcinoma

cases it was present only during swallowing, in other cases it was continuous While it occurred more frequently in the epigastrium, it was also related to various parts of the chest, chiefly retrosternal, lateral, interscapular and middorsal, and in a few instances it was complained of in the shoulder and down the arm In 61 per cent of the cases of stenosing and 40 per cent of nonstenosing tumors there was no pain Vomiting occurred in both types of patients at the time of admission to the hospital—in 14 per cent of the cases

TABLE 3—Symptoms

| | Stenosing | Nonstenosing |
|-----------------|-----------|--------------|
| Number of cases | 86 | 22 |
| Dysphagia | 81 | 3 |
| Loss of weight | 64 | 17 |
| Pain | 33 | 13 |
| Chest | 11 | 6 |
| Epigastrium | 20 | 0 |
| Back | 6 | 3 |
| Retrosternal | 4 | 1 |
| No pain | 53 | 0 |
| Vomiting | 12 | 6 |
| Regurgitation | 7 | 0 |
| Cough | 13 | 8 |
| Hoarseness | 6 | 3 |
| Weakness | 22 | 3 |
| Hematemesis | 0 | 1 |
| Tarry stool | 0 | 1 |

with obstruction and in 27 per cent without obstruction It transpired, however, following a close review of the case histories, that the rather surprisingly low percentage of the instances of vomiting in the cases showing obstruction could be accounted for, in part at least, by the fact that patients with obstructive lesions had gradually learned so to regulate the type and the amount of food taken as to avoid regurgitation and vomiting They progressed from solids to semisolids and finally to small quantities of liquid only They also limited their intake because of a loss of appetite and because of the development of pain in swallowing Food was not regurgitated in any cases in which there was no stenosis Cough was present in 15 per cent of the stenosing type and in 36 per cent of the nonstenosing Hoarseness was apparent in 7 per cent of the stenosing and in 13 per cent of the nonstenosing type

It can be said for the group as a whole that the blood picture, including both blood counts and chemical analyses, was highly variable, permitting no significant deductions and indicating no consistent trend There were of course some unusual manifestations in the blood studies, some of which may have been attributable to dehydration and to starvation Gross hemorrhage was conspicuous by its absence, hematemesis occurred in only one case, and tarry stool was observed in only one other

DIAGNOSES

Correct diagnoses were made in 92 per cent of the eighty-one cases of stenosis For the other seven patients the diagnoses recorded were mediastinal tumor,

TABLE 4—Diagnoses of Clinical Record in Twenty-Two Cases of Nonstenosing Tumors

| | Cases |
|---|-------|
| Carcinoma of esophagus | 2 |

| Cardiovascular disease (senile dementia) | 2 |

esophageal obstruction (not specified), carcinoma of the liver, carcinoma of the stomach (two cases), acute nephritis and pulmonary tuberculosis These errors in diagnosis were made in the case of persons who were not dysphagic and who were not studied roentgenographically with reference to the swallowing function The clinical impression for carcinoma was supported by characteristic roentgen changes in the greater number of stenosed patients Examination of biopsies in turn corroborated both the clinical and the roentgenologic opinion in respect to twenty-one patients In two other cases esophagoscopy was done, and the tissues obtained were reported as being of the chronic inflammatory type The tissues removed at autopsy, however, showed carcinoma

Chart 5—Average duration of symptoms according to cell grade in stenosing and nonstenosing tumors

The errors of diagnosis in table 4 are all explicable in the absence of dysphagia For instance, an emaciated patient with some febrile reaction and with equivocal signs in the chest might easily, in the absence of another explanation, suggest pulmonary tuberculosis And equally plausible reasoning might be applicable to others of these erroneously diagnosed cases One of the two correct diagnoses was reached because the patient evi-

denced a certain difficulty in swallowing during the last days of his illness. The other correct diagnosis was arrived at by roentgen study. This patient was one of four of the nonstenosing group for whom a complete roentgenologic study of the gastro-intestinal tract was made. Reports on three of these patients were negative for carcinoma of the esophagus. The fourth for whom the correct diagnosis was made had an annular type of lesion, adherent to the trachea, and registered delay in the time of transit of the barium sulphate meal.

GASTROSTOMY

Thirty-five patients had had gastrostomies performed at some time before death. The average length of life after hospitalization of the patients who were operated on was sixty-eight days, as compared with eighteen days for those not operated on. A majority of the patients who were operated on lived less than thirty days, and the greatest length of life after operation was 450 days.

The part that bronchopneumonia plays in the termination of life for these patients is noteworthy. Sixty-seven per cent of the stenosed patients died from this immediate cause. In some of these cases the pneumonia clearly developed from the aspiration of food.

SUMMARY AND COMMENT

A review of the data as presented makes it quite clear that the generally recognized description of carcinoma of the esophagus applies, in the main, to both

was of only moderate malignancy and that it was apparently of the same degree in the stenosing and nonstenosing varieties. It would also appear to follow that the grade of squamous cell carcinoma does not determine the stenosing and nonstenosing possibilities of a carcinomatous lesion in the esophagus. Grossly ulcerative lesions showed all grades of malignancy.

From the clinical point of view, these studies confirm the generally accepted belief that carcinoma of the esophagus is a rapidly malignant disease. This would seem to apply particularly to the nonobstructed patients whose brief course of illness was only approximately a third of the course of illness of the patients in the obstructed group. In this regard, however, some account should be taken of the fact that patients obviously found difficulty in establishing definitely the exact time of onset of symptoms.

On the whole, our analysis (chart 5) would seem to indicate no significant relationship between the grade of carcinoma and the duration of symptoms. This may mean that grading does not actually measure the degree of malignancy or it may mean that the duration of apparent symptoms in this disease is no real measure of the degree of malignancy. It is quite possible that a lesion in the esophagus, occupying as it does a relatively cryptic position, may in the case of the better differentiated tumor actually exist for a longer time than the symptoms seem to indicate. This is a reasonable inference if one judges by the life history of similarly graded tumors growing in easily observed locations, such as the skin and the cervix uteri. It seems reasonable to believe, on the basis of the studies here reviewed, that the clinical picture of esophageal carcinoma takes its character largely from the presence or absence of stenosis and is not dependent on the relative differentiation of the neoplastic squamous cell found under the microscope.

The outstanding implication is that the usual description of esophageal carcinoma has not sufficiently taken into account the nonstenosing variety, which very obviously cannot be responsible for difficulty in swallowing. In our patients with nonstenosing lesions the striking symptoms were loss of weight, pains in or about the chest, vomiting, cough and hoarseness. The loss of weight is apparently due to some subtle effect of carcinoma other than that resulting from a decreased caloric intake. In both the stenosing and the nonstenosing variety there would seem to be no direct relationship between the location of the carcinoma and the site of the pain.

It is probable that both varieties of lesions are fairly well advanced before symptoms become evident. Very early diagnosis is therefore rather a remote possibility unless a thorough investigation of the esophagus is made part of a periodic or otherwise routine examination, or unless the diagnostician has a lively and consistent recognition of the possibility that a patient with no difficulties in swallowing, with emaciation, perhaps with vomiting, with pain in the chest, cough and hoarseness, otherwise unexplained, may present this picture because he has carcinoma of the esophagus.

It may be pointed out that gastrostomy afforded in the cases reviewed very little extension of life beyond that of the patients who were not operated on. The failure of therapy thus far, together with the fatal outlook for this disease, should not discourage attempts at very early diagnosis, these sinister factors should, on the contrary, emphasize the need for calling into play at an early stage every diagnostic resource.

TABLE 5—Causes of Death

| | Stenosing | Nonstenosing |
|---|-----------|--------------|
| Number of patients | 66 | 22 |
| Carcinoma (uncomplicated) | 18 | 10 |
| Bronchopneumonia | 68 | 9 |
| Pulmonary tuberculosis | 5 | 0 |
| Postgastrostomy peritonitis | 2 | 0 |
| Suppurative mediastinitis with bronchopneumonia | 0 | 1 |
| Infiltration of aorta rupture fatal hemorrhage | 0 | 1 |
| Suppurative mediastinitis | 0 | 1 |
| Mediastinal abscess | 1 | 0 |
| Empyema | 1 | 0 |
| Postesophagectomy hemorrhage | 1 | 0 |

types. These studies corroborate the prevailing impression that men are more frequently afflicted than women, in a variable ratio. No evidence to account for this has been brought to light by this or by other studies. The age of the patients in the group studied here corresponds with the generally observed cancer-bearing years of life. As to race incidence, although our figures seem to suggest that the Negro is less likely than the white person to develop carcinoma of the esophagus, this study does not seem to furnish sufficient evidence for a conclusion in this regard. Nor can any decisive point be made concerning heredity, previous illnesses and habits of life as affecting the development of carcinoma of the esophagus.

The gross pathologic lesions observed in the group described are those generally recognized and the positions of these lesions are the positions heretofore generally noted. It is worth remarking, for further study or demonstration, that this particular study revealed not a single instance of a nonstenosing lesion in the upper third of the esophagus.

From the histopathologic aspect, if the Broders method of classification is also a measure of malignancy, it would seem that the cancer of cases reviewed here

CONCLUSIONS

1 Of the esophageal carcinomas in a series of 108 cases that came to autopsy, 20.3 per cent were of the nonstenosing type

2 Patients in this series with nonstenosing esophageal carcinoma presented weight loss, pains in the chest, vomiting, cough, hoarseness and weakness as outstanding symptoms. Dysphagia was distinguished by its relative infrequency, whereas in the stenosing group it was the dominant symptom

3 The sex, age and race incidence, the location of pain, the metastases, and the immediate causes of death were much alike in patients with stenosing and nonstenosing lesions

4 While clinically both the stenosing and the nonstenosing lesions were rapidly malignant, the clinical course in the nonstenosing group was only one third as long as that of the stenosing

5 Pathologically, these tumors were not particularly malignant, and there was no correlation between the grade of the tumor, the clinical course and the stenosing or nonstenosing tendencies

6 Whether roentgen investigation is positive or negative for this disease, the suspected patient should be subsequently studied by esophagoscopy, and, at the same time, properly selected tissue should be procured for histologic study. A single or even a subsequent report of failure to find tumor, however, should not be considered as finally precluding a diagnosis of carcinoma

Thirty-Fourth and Pine streets—1704 Pine Street

ABSTRACT OF DISCUSSION

DR. GABRIEL TUCKER, Philadelphia. The evidence presented is incontrovertible because it is obtained by necropsy. I should like to ask the authors whether postmortem examination showed gross evidence of stenoses in any case in which there had been no complaint of dysphagia. Clinically I have seen patients without any complaint of dysphagia when a routine roentgen study of the neck, chest and swallowing function showed the lodgment of a large capsule in the lower third of the esophagus. On esophagoscopic examination a nonstenosing lesion was found and biopsy showed carcinoma. The inspection of the lesion through the esophagoscope gives a characteristic appearance. One may see at times that the location of the lesion makes it inadvisable to do a biopsy. A negative biopsy should not be considered conclusive. The second, third or fourth biopsy may show cancer. The symptom of hoarseness is usually due either to involvement of the laryngeal nerve or in the stenosing type of cancer, to overflow of secretion from the pharynx producing inflammatory changes in the larynx. In hoarseness cancer of the esophagus is to be excluded as a possible etiologic factor. Esophagoscopy is a major diagnostic procedure and should be done with every possible precaution to avoid injury. The conclusions drawn by the authors from their studies should lead to earlier and more thorough examination of every patient for evidence of esophageal disease. Cancer of the esophagus should be recognized earlier. The advancement of the technique of irradiation and surgery of the esophagus leads to the hope that the authors have advanced one step nearer to finding a cure for cancer of the esophagus. A woman 39 years of age had marked obstructive symptoms in the esophagus. Roentgen examination showed a large dilatation of the esophagus with the typical picture of achalasia (so-called cardiospasm) with a stenosis at the level of the diaphragm. There was retention of a great deal of food in the esophagus and after lavage of the esophagus and thorough cleansing esophagoscopy was done and revealed a fungating ulcerating lesion on the left anterolateral wall about 5 inches above the level of the diaphragm. The esophagus at this level was so dilated that the fungating lesion did not come in contact with the wall of the esophagus

except at the point of its attachment and, although of considerable size was not obstructing the lumen of the esophagus. A biopsy showed the lesion to be cancer. At the time of the examination, the esophagoscope was passed into the stomach through the stenosed area at the level of the diaphragm and the typical picture of achalasia was found there being no lesion discernible. This case illustrates a nonstenosing type of cancer with esophageal stenosis due to achalasia, in which the esophagoscope was the only means by which a positive diagnosis could be made. However after the esophagus had been thoroughly cleansed the roentgen examination showed an irregularity in the anterior wall, with dilatation of the esophagus at the level of the cancerous lesion.

DR. TRUMAN G. SCHNABEL, Philadelphia. We were surprised after we had analyzed this group of autopsies to find that nonstenotic carcinoma of the esophagus had been present in 20.3 per cent. We had anticipated a short average clinical course for the 108 patients seven and a half months, but were particularly surprised that those of this series with nonstenotic lesions had lived only a little less than an average of three months after the onset of their symptoms. It was also surprising not to have found a correlation between the grade of the tumor according to the Broder classification, the length of the clinical course and the presence of a stenosing or a nonstenosing lesion. Tissue obtained by way of the esophagoscope may not show the malignant nature of esophageal lesions, particularly if dependence is placed on a single specimen. Esophagoscopy becomes more important when it demonstrates that esophageal dysfunction as exhibited by roentgen study is not due to an intrinsic lesion in the esophagus. I know of a patient who had a number of roentgen treatments, following what seemed to be positive roentgen evidence for carcinoma. Autopsy after sudden death demonstrated mitral stenosis with a large left auricle pressing on the esophagus. Here better roentgen studies and esophagoscopy would have established the correct diagnosis and therefore the futility of the treatment. After we had completed this analysis we saw a patient who had lost weight and who had unusually palpable cervical glands, some inequality of the pupils and hoarseness. With nonstenosing esophageal carcinoma fresh in our minds, we ordered roentgen investigation of the esophagus, even though there were no suggestive symptoms pointing to an esophageal lesion. The evidence from this source showed, what was borne out by subsequent biopsy investigation that we were dealing with carcinoma of the esophagus. A year ago the patient would have remained a diagnostic puzzle. The results of these studies should serve to remind one that carcinoma of the esophagus may not cause dysphagia. I should like to point out in answer to Dr. Tucker's question that five patients of this group with obstructing lesions did not complain of difficulty in swallowing. Long before patients present dysphagia as a symptom and even if they never refer to pain or difficulty in swallowing one should be conscious of carcinoma of the esophagus. Early roentgen investigation and esophagoscopy should be practiced to establish the presence or absence of this malady.

Too Many Mothers Make the Mistake—The period of menstruation is commonly referred to as the period of being 'unwell' and this is a rather unfortunate concept of the function. It is a perfectly normal phase and this is the idea of it which should be impressed upon young girls. Too many mothers make the mistake of impressing their daughters with the importance of coddling themselves during the periods, of abstaining from play and exercise at this time and, in short of actually considering themselves sick. As a consequence, because of the power of mind over body, many girls do actually become sick and develop into menstrual invalids of one sort or another as I shall have occasion to discuss later. This is particularly true if the mother, or perhaps an older sister, herself suffers with menstrual disorders of one sort or another, for the impressionable child just beginning to menstruate soon comes to look forward to each period as one when she must expect to suffer incapacity of one degree or another.—Novak, Emil. *The Woman Asks the Doctor*. Baltimore, Williams and Wilkins Company, 1935.

Clinical Notes, Suggestions and New Instruments

A NEW METHOD OF REMOVAL OF FOREIGN BODIES FROM STOMACH WITH THE AUTHOR'S SHEATHED FLEXIBLE GASTROSCOPIC FORCEPS

GABRIEL TUCKER, M D PHILADELPHIA

About a year ago I suggested and published a method of localization of foreign bodies in the stomach by means of roentgen examination by fluoroscopy and films following the introduction of an opaque feeding tube through the esophagus and the inflation of air into the stomach. This method has proved quite successful, and while using it it occurred to me that, if a flexible forceps should be devised that might be introduced into the stomach in the same manner as the feeding tube had been introduced for localization purposes, the removal of foreign bodies from the stomach could be carried out, and that, if this method should prove successful and a safe technic be developed, it would be very much simpler than the method of open tube gastroscopy now in use.

In foreign body removal the open tube gastroscope under double plane fluoroscopic guidance is generally used. In many cases great difficulty is encountered because the foreign body falls back alongside the spine in the left half of the stomach or on the right side of the spine in the pyloric end, where it is difficult to grasp through the gastroscope when the patient is placed in the usual dorsal recumbency for gastroscopic removal. Fluoroscopic guidance is always a necessity in the open tube method of gastroscopic removal of foreign bodies from the stomach. With the use of a sheathed flexible forceps, dispensing with a rigid open tube gastroscope, the patient can be

on the table until gravity and inflation of the stomach allow the foreign body to be grasped by the use of the sheathed flexible forceps under fluoroscopic guidance.

The sheathed flexible forceps (fig 1) that I¹ devised is of the cannula and stylet type with a modified handle and has a very strong and secure grasp. The flexible forceps is covered with a rubber tube sheath or jacket, the size of which is No. 18 French in the child size instrument and No. 20 French in the adult size. The sheath has attached to it a metal ball at the lower end, which is perforated for the passage of the forceps blades, at the upper end of the jacket is a slotted metal sleeve attachment that permits the adjustment of the jacket so that

Fig. 2—A, tooth plate in the stomach. B, sheathed flexible forceps grasping the artificial denture which has been withdrawn upward into the lower end of the esophagus. C, denture in the upper end of the esophagus. The grasp of the forceps covers the projecting point of the gold clasp. The curved clasp opposite was withdrawn through the esophagus without trauma. Roentgenograms by Dr. Karl Kornblum.

the forceps blades will be covered for introduction. After the forceps is introduced and fluoroscopic guidance indicates that it is in contact with the foreign body, the rubber tube jacket is drawn up about 1 cm and secured by the handle mechanism, allowing the forceps to protrude beyond the metal ball at the end of the jacket so that the foreign body can be grasped. The metal sleeve at the upper end of the rubber sheath is provided with an attachment that permits the introduction of air by means of a double bulb, so that the stomach can be inflated, thus releasing the foreign body from the folds of the stomach. The metal ball on the lower end of the rubber jacket guides the forceps around the greater curvature and prevents trauma during the introduction.

TECHNIC OF INTRODUCTION AND USE OF THE SHEATHED FLEXIBLE FORCEPS

In working out a technic for the use of this instrument I had the expert advice and invaluable assistance of Dr. Eugene Pendergrass of the Hospital of the University of Pennsylvania and of Dr. Karl Kornblum of the Graduate Hospital of the University of Pennsylvania. The entire procedure for removal of foreign body and introduction of the flexible forceps should be carried out under biplane fluoroscopic guidance, with the assistance of an expert roentgenologist with whom the endoscopist is accustomed to work. With adults a vertical plane fluoroscope of the motor driven tilt table type may be used. The patient is placed in the semirecumbent or upright position and rotated in front of the fluoroscopic screen giving biplane fluoroscopic guidance. For use in children, biplane fluoroscopic guidance in dorsal recumbency is necessary in order to control the patient. With the flexible forceps introduced into the stomach, however, the patient may be rotated so that gravity will carry the foreign body to a point at which it is accessible to the grasp of the forceps.

Introduction—In adults the sheathed forceps may be introduced like the ordinary stomach tube under fluoroscopic guidance. Previous roentgen study in all patients should exclude esophageal disease that would contraindicate introduction of the sheathed forceps. In children, when the patient is placed in dorsal recumbency, a child-size direct laryngoscope may be used to lift the cricoid forward so that the tip of the sheathed forceps

Fig. 1—The author's sheathed flexible forceps made by Geo. P. Pilling and Son Co., Philadelphia. A, flexible portion of the forceps coiled showing the degree of flexibility that will be permitted by the forceps. The blades are in the open position for grasping. B, the double bulb arrangement for inflation either for diagnostic examination or for assistance in grasping and removing a foreign body. Inflation may be carried out with the forceps blades either sheathed or unsheathed.

placed in the upright or semiupright position after the forceps is in position and gravity carries the foreign body to the greater curvature of the stomach, where it is easily accessible. In the case of a child in dorsal recumbency, the patient can be rotated

can be placed in the upper esophagus by sight. It is then gently passed downward and the laryngoscope removed. Further introduction is carried out under fluoroscopic guidance. This technique may be used also in the adult if any difficulty is anticipated. When the sheathed forceps has entered the stomach it is passed farther in until the metal tip comes in contact with the greater curvature of the stomach. If there is a question of the foreign body not being in the stomach, the stomach can be inflated through the sheathed forceps and the location of the foreign body with reference to the cavity of the stomach can be definitely determined by fluoroscopic observation. If the foreign body is in the stomach the patient can be rotated and the forceps manipulated until the metal end of the sheathed forceps is in contact with the foreign body. The sheath is then withdrawn sufficiently to allow grasping of the foreign body. The foreign body may be manipulated and turned until the proper grasp for withdrawal is obtained by inflation of the stomach with air through the forceps and manipulation with the forceps, the patient being rotated if necessary. Withdrawal of the foreign body after it has reached the hiatal esophagus is facilitated by slight inflation through the forceps with a hand bulb. Gentle traction is made and the additional air that has been introduced may produce regurgitation with consequent relaxation of the hiatal esophagus, and the foreign body will slip easily into the lower end of the esophagus while the hiatal sphincter is relaxed. Sufficient time for the hiatal sphincter to relax while gentle traction is made is necessary to avoid trauma. When the foreign body has been brought into the upper end of the esophagus, the laryngoscope may be reintroduced over the sheathed forceps and the cricoid lifted forward. During the introduction and use of the forceps a trained assistant to hold the head and another assistant to maintain the

Fig 3—Gold denture removed from the stomach with the sheathed flexible forceps

position of the shoulders are necessary in addition to the fluoroscopic aid of an expert roentgenologist.

Caution—Extreme gentleness should be used and plenty of time allowed for the musculature of the esophagus to relax during all manipulations to prevent trauma. With the use of the sheathed flexible forceps, as in all examinations

and treatments of the esophagus haste and undue force have no place. They will result in disaster. Even the ordinary stomach tube will rupture the esophagus if sufficient force is used in introduction.

REPORT OF CASES

The method has not been in use long enough to establish definite conclusions. However a number of foreign bodies have been removed without any difficulty and the reports of two cases are submitted.

CASE 1—A physician, aged 63 dislodged a gold dental bridge containing two teeth while eating his breakfast two weeks before he came to me for removal of the foreign body. Repeated roentgen examination before admission showed the denture in the stomach. It apparently would enter the pyloric end of the stomach and then be regurgitated into the stomach not passing through the pylorus. I explained to the physician my new forceps and method of removal and he requested that I remove the foreign body from the stomach by this method. The patient was placed on a fluoroscopic motor driven, tilt table and the forceps was introduced in the same manner as the ordinary stomach tube. Under fluoroscopic guidance by Dr Karl Kornblum the gold denture could be visualized in the stomach at the greater curvature (fig 2 A). The sheathed forceps was introduced until the tip came near the foreign body. A small amount of air was then insufflated and the foreign body was released from the stomach folds and was easily grasped by one of the sharp points of the clasp that had been constructed to hold the denture in place in the mouth. This grasp on the foreign body protected the sharp points, making it safe for withdrawal through the esophagus. As the

foreign body was withdrawn to the level of the diaphragm a small quantity of air was insufflated, and the foreign body came easily into the esophagus. Slight difficulty was encountered as the foreign body was brought through the cricopharyngeus but it came readily through the esophagus without trauma (fig 2 B and C). The procedure required only a few minutes the patient experiencing only slight discomfort.

CASE 2—A baby girl, aged 6 months, admitted to the Graduate Hospital of the University of Pennsylvania, choked on

Fig 4—A sheathed flexible forceps grasping the open safety pin in the stomach in a child aged 6 months. B open pin after cephalic version withdrawn into the lower end of the esophagus with the sheathed flexible forceps. Roentgenograms by Dr Karl Kornblum.

safety pin the night previous to her admission. Roentgen examination showed the pin to be in the esophagus just entering the stomach. The child was placed on a fluoroscopic table, and the child size sheathed flexible forceps was introduced. As the forceps passed downward in the esophagus the pin passed on to the greater curvature of the stomach. The forceps was introduced into the stomach, a small amount of air insufflated and the pin manipulated with the forceps. The sheath of the forceps was retracted so that the pin could be grasped with the rotation blades in the ring (fig 4 A). A cephalic version was done with the pin and it was withdrawn with the point downward (fig 4 B). Slight difficulty was encountered in getting the pin out of the pharynx, and in my future case in an infant I should introduce a laryngoscope into the hypopharynx and lift the larynx and base of the tongue forward as the pin comes through the upper end of the esophagus (fig 5).

COMMENT

1 It is believed that the proposed method of removal of foreign bodies from the stomach with the author's sheathed flexible forceps is safe and effective and will produce less discomfort than the ordinary method of gastrosopic foreign body removal.

2 Owing to the fact that air can be insufflated through the forceps, the operator can at all times determine readily the position of the foreign body with relation to the cavity of the stomach, and the stomach folds can be obliterated so that the foreign body can easily be grasped.

3 The instrument should be used by those who are experienced in endoscopic work and intraesophageal manipulations. Biplane fluoroscopic guidance with the aid of an expert roentgenologist who has developed with the endoscopist a team for the removal of foreign bodies under fluoroscopic guidance is an indispensable part of the technique.

4 Because of the fact that the patient can be rotated and the position changed with safety while under fluoroscopic observation the method will permit the removal of foreign bodies that would be inaccessible to the ordinary gastrosopic method.

AN OUTBREAK OF FOOD POISONING APPARENTLY DUE TO STAPHYLOCOCCI

G M DACK PH D M D CHICAGO

GEORGE W BOWMAN M D

State Medical Director Indiana Transient Service Activities

AND

R. N HARGER PH D, INDIANAPOLIS

A number of outbreaks of food poisoning due to staphylococci have been studied in recent years. Jordan and Burrows¹ have cited nine such outbreaks.

The outbreak reported here is of interest since it involved a large number of people (206) and since specimens of food collected immediately following the illness were refrigerated and later frozen, so that the bacteriologic analyses are representative of the foods at the time of consumption.

A recent outbreak of food illness occurred in a group from one of the shelters of the federal Transient Service Activities in Indianapolis. The men affected were only those on outside work relief projects. The menu, outlined by a trained dietitian, was served throughout all transient centers in the state with identical foods, the same meat, from the same source lots of food products of standardized quality from recognized reputable packers. The outbreak did not occur or recur in the other shelters in the same city. Lunches were prepared for these men on Thursday, June 13, 1935 between midnight and early morning. The lunches consisted of sandwiches wrapped in wax paper, which were put up in bags and given to the men in the morning when they were sent out on work relief projects. Records were obtained from 206 men who were ill and 161 who were not ill although a total of 471 men were sent out with the same lunch. The lunches were eaten at about 11:30 a. m., and about 2 p. m. of the same day the men affected were seized with epigastric distress, vomiting, diarrhea and marked prostration, the acute symptoms lasting for several hours.

A sharp rise in temperature following a long period of rain came during the day (90° F.) as a contributory factor. The ingestion of varying grades of alcohol from canned heat, but not always admitted on interview, malingering, and the psychic element were no doubt also contributory factors. One other suspicious factor was a much used driven well near an old fish pool in a nearby city park. Although not dangerously contaminated or unsafe for drinking purposes, it has since been closed.

The epidemiologic data are summarized in table 1.

From a study of table 1 it is obvious that the greatest number of men were ill in the group eating the tongue sandwiches. Since 206 men became ill and 187 of this number ate tongue sandwiches, the difference of nineteen must be explained. Gastro-intestinal upsets might well have occurred in this small number (nineteen) simply from being with the others who were so violently ill.

A thorough general chemical analysis of all mentioned foods for extraneous poisons was negative, this analysis was made by one of us (R. N. H.).

A bacteriologic examination was made of the following specimens:

- | | |
|--|--------------------------------------|
| 1 Pickle | 9 Fig |
| 2 Scraps of bread from sandwiches | 10 Sugar |
| 3 Jelly sandwich | 11 Cream—evaporated milk |
| 4 Jelly used for preparing sandwiches | 12 Coffee |
| 5 Tongue from sandwich | 13 Vomitus |
| 6 Crumbs of bread from tongue sandwich | 14 Cheese |
| 7 Cheese sandwich | 15 Peanut butter from sandwich |
| 8 Tongue—stock used in making sandwiches | 16 Bread from peanut butter sandwich |

Portions of the solid specimens were emulsified in sterile salt solution. One small loopful of each specimen was streaked on blood agar and eosin methylene blue agar plates. Serial dilutions were made and pour plates prepared, veal infusion agar and eosin methylene blue agar being used. The plates were

incubated for twenty-four hours and then examined. Some of the plates showing no growth were incubated for an additional period of twenty-four hours, after which they were again examined.

Numerous hemolytic *Staphylococcus aureus* colonies were present on the blood agar plates streaked with samples 2, 3, 6 and 8. These staphylococcus colonies predominated over all others in the plate containing specimen 2. No paratyphoid organisms were found on any of the eosin methylene blue agar plates. No growth occurred on the eosin methylene blue, blood agar or veal infusion agar plates inoculated with samples 1, 4, 10, 11 and 12. Green streptococci were present in samples 7 and 9. No organisms of known significance were found in any of the other samples.

TABLE 1—Epidemiologic Data

| Food | Ill | Not Ill | Total |
|------------------------|-----|---------|-------|
| Tongue sandwich | 187 | 85 | 272 |
| Peanut butter sandwich | 148 | 123 | 271 |
| Cheese sandwich | 162 | 126 | 288 |
| Jelly sandwich | 167 | 149 | 316 |
| Coffee and cream | 127 | 104 | 231 |
| Coffee without cream | 14 | 13 | 27 |
| Pickle | 133 | 101 | 234 |

The large number of hemolytic yellow staphylococci in the scraps of bread from the sandwiches and the presence of these organisms in the tongue, together with the statistical data on the foods eaten, seemed further to incriminate the tongue sandwiches as the source of the food poisoning. Strains of these staphylococci were therefore isolated from samples 2, 6 and 8. These cultures were tested for food poisoning toxic substance by feeding experiments on *Macacus rhesus* monkeys. For this purpose the cultures were inoculated into 1 per cent veal infusion agar, pH 7.0, and grown in an environment of about 25 per cent carbon dioxide for thirty-nine hours at an incubation temperature of 37° C. After incubation, the agar was removed by filtering through cheese cloth, and the remaining liquid culture was fed to the monkeys. Each culture was fed by stomach tube to two monkeys. The results are listed in table 2.

TABLE 2—Results of Culture

| Monkey | Culture from Specimen | Amount Fed | Results |
|--------|-----------------------|--|--|
| 1 | 2 | 4 cc | Vomited 40 minutes after feeding |
| 2 | 2 | 40 cc | Several paroxysms of vomiting beginning 2½ hours after feeding |
| 3 | 6 | 55 cc | Several paroxysms of vomiting beginning ½ hour after feeding |
| 4 | 6 | 50 cc ? | No reaction in 4½ hours |
| | | Much of sample regurgitated at time of feeding | |
| 5 | 8 | 40 cc | Several paroxysms of vomiting beginning 25 minutes after feeding |
| 6 | 8 | 48 cc | Vomited 3½ hours |

The results obtained by feeding cultures of the yellow hemolytic staphylococcus isolated from the scraps of bread (sample 2), the crumbs of bread from the tongue sandwich (sample 6), and the tongue used in making the sandwiches (sample 8) indicated that these strains were of the food poisoning type.

The presence of the food poisoning type of hemolytic yellow staphylococci in the tongue could well account for the distribution of this organism in the sandwiches. The absence of this organism in the cheese sandwich (sample 7) and the bread from the peanut butter sandwich (sample 16) would indicate that the bread was not the source of these organisms. When proper conditions of moisture and temperature occur, the organisms probably spread into the bread from the meat filling of the sandwich. This spread of the bacteria is associated with growth of the organism with apparent elaboration of the toxic substance responsible for food poisoning. Favorable conditions for the development of this organism were not attained in all cases, since many of the men eating tongue sandwiches did not become ill.

There were no fatalities directly traceable to the food poisoning, although one death followed about a week later from pneumonia. All made a rapid uneventful recovery within a few hours.

From the Department of Hygiene and Bacteriology, University of Chicago, and the Department of Biochemistry and Pharmacology, Indiana University School of Medicine.

¹ Jordan, E. O. and Burrows, William. *Am J Hyg* 20: 604 (Nov.) 1934.

CONCLUSION

A food poisoning outbreak involving 206 men was apparently due to eating tongue sandwiches that were contaminated with a yellow hemolytic staphylococcus. The staphylococci were shown by monkey feeding experiments to be of the food poisoning type.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE AND REPORT

HOWARD A. CARTER, Secretary

LIGHT THERAPY AND ROENTGEN THERAPY IN TUBERCULOSIS

PRESENT EVALUATION

EDGAR MAYER, M.D.

NEW YORK

Light therapy, both natural and artificial, is of definite value in the treatment of some forms of tuberculosis. There is still considerable difference of opinion on which regions of the light spectrum are most efficacious, as well as confusion as to the tuberculous conditions that respond best to this treatment.

Natural heliotherapists, especially those working in high altitudes, emphasize solar radiation and aërotherapy. On the other hand, those in cloudy climates have stressed the use of artificial lights and still others, on occasion, the x-rays.

CLINICALLY EFFECTIVE SPECTRAL REGIONS

There is much dispute as to the relative therapeutic values of infra-red, visible and ultraviolet rays, but, unfortunately, most observers, enthusiastic over their own results, seem to be biased in their opinions. The effective heat rays of the light spectrum lie at the red end and include visible red and invisible infra-red rays, while actinic rays found at the other end comprise that visible region extending from the blue, through indigo, violet and the invisible ultraviolet rays.

Sonne found that the infra-red heat rays from the carbon arc light set up a cutaneous erythema leading in animals to the production of blisters through rapid elevation of the skin temperature. The luminous heat rays, on the other hand, without producing bodily fever could heat a very essential portion of the aggregate blood volume of the body to a temperature possibly exceeding the highest bodily temperature ever measured. Those stressing therapeutically the heat radiation have described experiments in which animals whose body temperature has been elevated to a high degree have shown extreme tolerance of infection. Rabbits subjected to exposures of dry heat sufficient to increase activity of the lymphoid organs have been shown to develop on immunization antibodies in much larger quantity than did untreated animals immunized in the same fashion.

Danish workers stress particularly carbon arc radiation for all types of tuberculosis. This arc emits much visible red and invisible infra-red energy. Its total visible rays furnish energy equal to about 20 per cent of its aggregate radiant energy, and this is increased proportionately with its ampere volume.

Hyperemia due to heat radiation has been credited with favorable clinical results. Bier and others

employed heat lamps at high temperatures which produced hyperemia of long duration and elevated the cutaneous temperature to that produced by sunlight, rapid clinical recoveries ensued.

Bernhard of St. Moritz, a pioneer in solar therapy, never filters out the infra-red in his treatment of wounds. He ascribes his recoveries to the green-yellow and shorter infra-red rays. This was borne out by poor results of wound healing obtained with ultraviolet rays emitted by the mercury vapor arc in quartz.

The physiologic effects of radiant heat energy suggest that clinical results of therapy with sunlight are at least in part dependent on the red and infra-red region.¹ Most recently the response of certain forms of superficial tuberculosis, especially of the skin, to heat radiation, speaks very clearly for this.

The exact part played in the clinical usage of light by the total visible spectrum is difficult to say, although in all probability it is in some way physiologically effective.

The role of ultraviolet energy has been much more definitely established through animal and human studies in calcium-deficient diseases in which it has specific effect. Furthermore, in tuberculosis, on the basis of the quality of ultraviolet wavelengths and of the results obtained at the seashore, at inland sea level and in the mountains, Danish workers are convinced that ultraviolet energy of the region longer than 313 millimicrons is the one effective in the treatment.

The additional part played by the action of moving air on the skin in the solar treatment of extrapulmonary tuberculosis must not be discredited. Probably the combination of all factors contributes to the end result.

MERCURY VAPOR ARC IN QUARTZ COMPARED WITH CARBON ARC LIGHT²

The radiations of artificial sources represent approximations to sunlight and no two sources are alike in respect to the distribution of the energy they emit. Therefore different sources do not produce the same physiologic or therapeutic action. The energy emitted by various artificial sources varies in intensity and in spectral distribution. The intensity of the radiation of sunlight on the earth's surface varies considerably, particularly on account of location, season and time of day. It will vary as much as 5 per cent in total intensity and a variation of 5 to 10 times in noon-hour ultraviolet winter to summer.

In the choice of an artificial source of light, one must consider the quantity and quality of the energy emitted by the lamp. A sufficient quantity of radiation must be present which corresponds to the particular parts of the spectrum found most efficient in the disease to be treated. Under different conditions all parts of the light spectrum will yield results if particular conditions demand the wavelengths that a special source of light emits strongly.

For therapeutic purposes the sun, the mercury vapor arc in quartz and the flaming carbon arc burning cored carbons filled with mixtures of carbon dust and metals have been the chief ones of practical importance. The mercury vapor lamp has been particularly developed for its emission of ultraviolet, although it emits also well in the visible part of the spectrum. Its ultraviolet component represents between 9 and 28 per cent

¹ Pemberton, Ralph. Influence and Therapeutic Use of Heat. *J. A. M. A.* 105:275 (July 27) 1935.

² Laurens, Henry. Factors Influencing the Choice of a Source of Radiant Energy. *J. A. M. A.* 103:1447 (Nov. 10) 1934.

of the total energy of all wavelengths emitted by the lamp. A carbon arc consuming 25 amperes or more and burning specific carbons, such as "sunshine" carbons, closely approximates highland sunshine. Carbon arcs of varying amperage and with special cored carbons will emit, almost according to the needs, widely varying intensities in many regions of the light spectrum.

An important question in the selection of these various sources of light is the minimum ultraviolet radiant power that a source must emit in order to insure effective therapeutic action. The amount of ultraviolet that can be applied to the body without producing a burn depends on the tolerance of the skin. The erythema reaction is really the only physiologic one that is established with a relatively high degree of accuracy. As a criterion it is a simple and practical means of preventing severe burns and as a reaction it is a good means of judging the effectiveness of a lamp.

Exact clinical indications for different sources of light have not yet been defined. For rickets and tetany, both the carbon arc and the mercury arc as well as sunlight have proved curative. For extrapulmonary tuberculosis, as that of the skin, bones and joints, intestine, peritoneum and lymph nodes, both sources of light have had strong adherents and both have shown their value. The enthusiasts for solar treatment will insist that a spectrum closely approximating that of sunlight is necessary, and therefore they particularly advocate certain carbon arcs. Others who have gotten favorable clinical results with mercury quartz lights argue in their behalf.

The conditions, clinical and otherwise, indicating the selection of one source of light in preference to others depend in part also on the convenience of usage, the availability of the source of light, and the cost of running. In the past, carbon arc lamps of high amperage have been more generally applied for exposures of groups. The mercury quartz lights are now applicable for exposures of groups as well as individual patients. The carbon arcs of lower amperage, as well as mercury arcs, can be used for single patients. Irradiation with artificial light, as ordinarily employed indoors, lacks some apparently important accompaniments of outdoor solar exposures, such as constantly moving fresh air with its deeper effects produced through the skin and respiration, and in colder weather the uniform warming of the whole cutaneous surface with its production of a sense of comfort, well being and relaxation. Workers aim to produce this with artificial sources of light and some added means of ventilation indoors.

PULMONARY TUBERCULOSIS

For uncomplicated pulmonary tuberculosis, no clinical evidence is at hand to prove the indication for light therapy. The lack of accurately controlled observations among certain workers makes it necessary to accept their favorable reports most cautiously. Until contrary evidence is at hand, uncomplicated exudative pulmonary tuberculosis is a contraindication to light therapy, with proliferative or fibrotic pulmonary tuberculosis, which may be accompanied by elevation of temperature, sunlight or artificial lights, if employed at all, should be used cautiously. Intense sunlight should be avoided, and diffuse daylight or early morning and late afternoon sunlight should be used. Focal or constitutional reactions should be watched for. The indications here resemble those of tuberculin therapy.

In pulmonary tuberculosis, even when quiescent, harm has been done by sunlight exposures, especially with too intense and prolonged irradiations. Solar heat alone, especially in summer, can prove very exhausting. An observing patient will note fatigue, exhaustion, irritability or even overstimulation after these solar baths. With this reaction, sunlight should be discontinued. If symptoms are due to overdosage only, exposures may be resumed after an interval, shorter or less intense exposures being employed. Increase of local symptoms, such as cough and expectoration, and pleurisy, or of systemic symptoms, such as elevated pulse and temperature, serves as a guide. In these cases it may be advisable to substitute irradiations of diffuse daylight of longer duration, or of low intensity sunlight in the early morning and late afternoon hours.

A moot question is the exposure of active febrile pulmonary tuberculosis, with or without extrapulmonary complications, to light irradiations. As regards x-ray exposures, workers with extensive experience caution strongly against irradiating exudative pulmonary tuberculosis but emphasize as suitable only the stationary proliferative and fibrotic forms with little or no fever. Do similar indications hold for light radiation?

Lo Grasso and others have employed sunlight of weak intensity (in the early morning and late afternoon hours) for uncomplicated febrile pulmonary tuberculosis and have claimed favorable results. On the other hand, the reports of Bronfin from the sunny resort of Denver and of Jacquerod in Leysin, Switzerland, contradicted this. My own experience is strongly in agreement with the latter.

In an active febrile pulmonary tuberculosis complicated by active intestinal tuberculosis, mercury quartz irradiations have been regularly used by many for the intestinal complication and not infrequently with favorable effect. In such cases the activity and nature of the pathologic changes of the pulmonary disease have been disregarded. The favorable empirical results thus obtained and the poor results obtained when other treatments have been used justify this as an indicated therapy.

For other forms of active extrapulmonary tuberculosis, such as that of bones and joints, or lymph nodes complicating active pulmonary tuberculosis, light exposures have been often used to advantage, so that the pulmonary disease, if not rapidly progressive, offers no contraindications. However, careful observations, especially in exudative forms of pulmonary disease, will not rarely reveal the development of harmful pulmonary focal reactions due to excessive exposures to light. This should deter one from exposing such patients indiscriminately.

Focal reactions have been shown to occur in the lungs, even when direct sunlight is reflected in overdosage on a tuberculous larynx. Some workers observed their occurrence when the limbs alone were irradiated with the mercury quartz and carbon arc lights. In the use of both lamps and sunlight, one often notices on beginning treatment a slight elevation of temperature with mildly increased focal pulmonary symptoms. This reaction has been likened by some observers to a tuberculin reaction. Jesonek believed that the pigment could act specifically, just as tuberculin, and that when carried by the blood it set up a focal reaction such as he had observed in the lungs, larynx and joints. He obtained these only in cases in

which good pigmentation developed, and a latent period always existed before signs of the reaction appeared. By the screening of lupus areas from the light and exposing the rest of the body, the diseased tissue has often healed, indicating apparently the transport by the blood of some substance to the focus. However, therapy is preferably carried out by exposing the diseased parts in addition, because the local inflammatory reactions obtained through direct irradiations may be of importance.

In tuberculosis of the urinary bladder, under general irradiations, small nodules have been reported to develop in the bladder, which were considered as focal reactions. In animal experiments irradiation of the posterior part of a frog's body produced vascular changes in the retina. Isolated instances of disappearance of tubercle in the retina under general irradiation have been cited. Reyn and Strauss found that thirty cases of lupus, which had not been affected by previous local treatment, healed when general irradiations were added.

After an experience of eight years with irradiation from the mercury quartz lights of 655 patients in all stages of tuberculosis and with thousands of exposures, Godde reported definite focal reactions set up in fifty-seven of them, manifested by an increase of constitutional symptoms and a spread of the pulmonary disease. He was strongly of the opinion that quartz light treatment was not a harmless procedure and might do damage unless the irradiations were carefully graded and slight reactions were heeded. Other workers, including Marfan, Grau, Brecke, Bacmeister and Harms, have similarly warned against such focal reactions.

Harm due to irradiation of patients with pulmonary tuberculosis results almost always from an indiscriminate use of light, with overdosage. It manifested itself in my experience with increased local symptoms, namely, increased cough and expectoration, localized pain, blood-streaked sputum or hemoptysis, and, following these, fever and tachycardia. The exposures had then to be shortened, discontinued or given over less surface of the body. I have seen genito-urinary tuberculosis become definitely aggravated because of overexposure.

Even though only occasional undue focal reactions happen, caution is justified. They can easily be avoided. Their importance has been emphasized to warn against careless usage of light with little regard for dosage.

Roentgen therapy of pulmonary tuberculosis is effective for the proliferative and fibrous forms when the disease is stationary. The response is characteristically slow. Exudative tuberculosis is a contraindication. Overdosage produces damaging focal reactions, often of caseous pneumonia. The best results are had with doses of about three fourths to four fifths of an erythema dose. The quality of the rays should vary according to the depth, extent and nature of the pathologic condition. Tumor or tolerance doses should not be used for tuberculosis.

PLEURAL TUBERCULOSIS

Pleural tuberculosis, dry or serous, especially if it is the initial clinical manifestation, is occasionally aided by light therapy. The acute serous form is not to be irradiated. A tuberculous pleurisy with no obvious pulmonary disease usually responds to ordinary rest and hygienic-dietetic treatment, those cases not responding after about a month of such treatment may

call for irradiations. Pleurisies occurring in the course of obvious pulmonary tuberculosis, as well as pneumothorax cases, offer the same indications as the lung disease. Tuberculous empyemas do not respond. If sinuses are present, they are rarely helped by local and general light applications. Pleural tuberculosis in the Negro, peculiarly enough, has been cited as favorably responsive to light.

LARYNGEAL TUBERCULOSIS

Laryngeal tuberculosis is practically always secondary to pulmonary tuberculosis, so that the indications for the treatment of the larynx depend on the nature of the disease in the lungs. Here, again, light by itself is not curative but exercises its part only as an adjuvant to the other mainstays of treatment. These, in addition to the enforced rest and hygienic regimen, include local measures to the larynx applied as they are indicated. Such local measures in particular include absolute vocal rest (silence), local medications and sprays, and local application of the galvanic cautery. General light exposures are made to the body, with at times additional laryngeal local exposures. The acute forms of laryngeal tuberculosis, particularly those with edema, are not indications for light therapy.

Often vocal silence and bodily rest comprise the only treatment required for healing this complication of pulmonary tuberculosis. A large percentage of the patients will get well in this way and frequently, therefore, the irradiation employed is unjustifiably credited with the result. If these measures have not brought about improvement in the larynx within a reasonable time, light exposures are indicated.

Local exposures of sunlight may be made by means of metallic reflectors (chiefly magnalium). With artificial sources, local irradiation has been carried out by reflected light through special means devised to employ the maximum intensity of ultraviolet or by direct irradiation through quartz applicators attached to water-cooled mercury arcs or through especially constructed direct water-cooled sources of light. Exposures are made with the aim of producing a mild focal reaction, the reaction being allowed to subside before the next exposure is made. Those patients in whom mild focal reactions developed through irradiation showed often a greater tendency to heal, but no advantage to be gotten from a local treatment to the larynx is cause enough to compel a patient to leave his bed when his active disease indicates bed rest. Furthermore, general body irradiation in this complication plays a large part.

Direct local exposures have been made with a special carbon arc through a Seifert apparatus, originated at Hayek's clinic in Vienna. This is a direct irradiation procedure in which the epiglottis is elevated and the pharynx and larynx are narcotized as for direct laryngoscopy. The patient (lying down) then receives direct exposure of the larynx, ranging from one to fifteen minutes, depending on the stage of treatment and the reactions. Exposures are made generally biweekly and extend over a period of a year or more. The results with all these local irradiating methods must still be adjudged with caution.

The electrocautery is one of the best methods of treatment in laryngeal tuberculosis and is the form of local treatment most used by laryngologists with experience in handling this disease. Local light therapy has proved useful as a postoperative measure in cauterization cases, and as a sedative measure in cases in which cauterization cannot be done.

involved, and whether the disease is caseous or fibrous. At times complete radical excisions of the whole tract or the major part of the tract are indicated.

BONE AND JOINT TUBERCULOSIS

In bone and joint tuberculosis, heliotherapy, although not the mainstay of treatment, is always employed in combination with other forms of therapy. Orthopedic measures, rest in the open and light form the basis of conservative therapy.

Combined conservative treatment includes orthopedic measures, such as immobilization of joints, traction, and careful use of passive and active motion, use of light, air, tuberculin and diet, judicious application of surgery, and, rarely, roentgen therapy.

There are at present three definite schools of treatment, each with adherents. The first emphasizes the need for surgical intervention, especially fusion, in all cases of joint tuberculosis. This school maintains that cure can occur only through ankylosis and that this ankylosis is produced more rapidly and safely by the surgeon than by nature.

The second school, as represented by Rollier, is rigidly set against surgery except in unusual instances. This school holds that light therapy with orthopedics can do far more than the surgeon's knife. The latter destroys while radiation heals.

The third school adopts a more conservative attitude. Its leaders think that the problem of joint tuberculosis is much too complicated and difficult to be settled by one mode of attack and that in each instance numerous points of view and fine differentiations must be considered in reaching the maximum therapeutic effect. Surgery, solar therapy, artificial light therapy, braces, even in some cases the much maligned plaster-of-paris cast, all have their place in the treatment of bone and joint tuberculosis. Only the future can decide which of these three schools comes nearest to the truth, although advocates of surgical fusion are steadily increasing.

Light therapy must be admitted to be a real addition to our resources. It is not to be expected that it will produce new cartilage in place of that which has been utterly destroyed, it does not make the process of fusion less necessary than it has been hitherto, but it can help this develop. It is wrong to expect that its use will bring about regeneration of bone equal to that of a few vertebral bodies when they have been destroyed, but when this has occurred and a gibbous deformity exists, light therapy has aided orthopedic treatment in fusing these diseased surfaces, especially when employed together with postural treatment.

Surgical fusions are less commonly performed on children under 12 years of age. If performed on adults or children, the disease must first show some evidence of retrogression, thus surgery is to help nature. Following operation, patients are still treated for from one to two years, and during this period heliotherapy plays an important part.

Both mercury arc in quartz and carbon arc irradiations, employed as general and local exposures for prolonged periods of time, have proved aids in the treatment of bone and joint tuberculosis. The technic of irradiation is the same as that described with other forms of tuberculosis. With early exposures, the joints or bones often respond with increase of the local swelling and pain and, if a sinus is present, increased secretion. These in turn subside. Small joints yield more quickly to treatment than large ones. The knee joint is

refractory, and particularly obstinate are old fistulas of the spinal column, pelvis or hip. Treatment demands two years or more in many instances.

Roentgen therapy is occasionally added and has at times shortened the period of treatment. As a rule, however, it is not enthusiastically advised except in involvement of the smaller and superficial bones, those of the tarsus, metatarsus, carpus, metacarpus, fingers and toes, sternum and ribs. Even with these, results are not rapidly obtained. In tuberculosis of the spine, hip, knee and sacro-iliac joint, x-rays are practically never used.

OTHER FORMS OF TUBERCULOSIS

Various other forms of tuberculosis indicate light therapy. With the cutaneous tuberculosis, lupus vulgaris responds almost specifically. Scrofuloderma and erythema induratum react less constantly but very favorably at times. Papulonecrotic tubercles are resistant. Lupus erythematosus is often aggravated by light. Tuberculous ulcers of the mouth and pharynx, usually secondary to advanced pulmonary or laryngeal tuberculosis or to hematogenous dissemination, are most resistant. Electrocoagulation is a more effective therapy.

X-rays are of definite value in most cutaneous tuberculosis due directly or indirectly to the tubercle bacillus and in a few results are spectacular.⁴ Those which are amenable to x-rays respond well to suberythema or sub-intensive and fractional dosage. Suberythema doses of from one half to two thirds of a skin unit, repeated in a month or more, give excellent results in scrofuloderma and disseminated miliary lupus. This method of irradiation, alone or combined with various medical and surgical methods, benefits or cures also lupus vulgaris, sarcoid, erythema induratum, tuberculosis orificialis and tuberculosis verrucosa cutis. The tubercles and lupus erythematosus temporarily involute under x-rays, but recurrences are not prevented.

Aural and ocular tuberculosis are difficult to affect with light, although corneal ulcers and phlyctenular conjunctivitis have not infrequently healed under local exposures. Roentgen therapy has proved effective with tuberculosis of the cornea and iris, but its dose must be moderate and repeated regularly at intervals of about four weeks. These measures are indicated when tuberculin therapy has failed.

RELATIVE MERITS OF DIFFERENT FORMS OF RADIATION

The following outline is constructed with the realization that as yet the relative merits are not accurately defined and not accepted by all. It is offered merely as a possible working basis.

Sunlight is available in almost every locality at some season of the year. Its intensity is variable, but moving air and low intensity sunlight or diffuse daylight can generally be used. In some places, where the extreme cold of winter prevents outdoor exposures for a few months, artificial sources of light should be resorted to.

1 *Uncomplicated Pulmonary Tuberculosis*—(a) Sunlight is to be used only after prolonged trial of routine rest, hygienic-dietetic treatment, and perhaps in cases in which surgical treatment has failed to cause satisfactory healing (exudative tuberculosis always excluded). Carefully graduated general body exposures are to be made to sunlight of low intensity or to diffuse daylight, together with air baths in the earlier morning or later afternoon hours. The so-called pre

⁴ MacKee, G. M. Cutaneous Roentgen and Curie Therapy. *Science of Radiology* 1933, p. 291.

tuberculosis of children, as well as chronic pleurisies, are all forms in which sunlight can be the treatment of choice

(b) Artificial lights (mercury arc in quartz and carbon arc) deserve a trial only after routine therapy has failed, but one should not expect promising results except in isolated instances. They may occasionally help as an adjuvant. Progressive cases with fever and exudative tuberculosis are excluded. Pleurisies and the "pretuberculosis" of children can be favorably influenced.

(c) X-rays are to be confined to the proliferative and fibrotic forms with little or no fever, and then used rarely, if at all. Progressive pulmonary tuberculosis and all exudative forms strongly contraindicate x-ray exposures.

2 Active Extrapulmonary Tuberculosis Without Active Pulmonary Tuberculosis—Tuberculosis of the skin, lymph nodes, bones, joints, genito-urinary tract, peritoneum, intestine. By this is meant that the signs and symptoms of active or progressive disease are due, not to the pulmonary tuberculosis, but to the extrapulmonary focus. Signs of active disease include both local and constitutional signs.

(a) Sunlight is the treatment of choice for bones and joints, lymph nodes and genito-urinary tract, especially in the highlands. Graduated exposures of the body are to be made to sunlight, together with the use of rest and hygiene and whatever surgical and orthopedic measures may be necessary. Results are excellent if sunlight is employed over prolonged periods, even in active but not rapidly progressive forms of the disease. Artificial lights should be used, in addition, on cloudy days, especially in cases of cutaneous tuberculosis or discharging sinuses.

(b) Artificial lights (mercury arc in quartz and carbon arc) are to be used usually as substitutes for sunlight. However, they may be preferable to sunlight for certain complications, such as superficial, peritoneal and intestinal tuberculosis. Superficial forms include lupus vulgaris and scrofuloderma, keratitis and phlyctenular conjunctivitis. General exposures are always made with additional local exposures over the area of disease.

(c) Roentgen therapy may be the treatment of choice in the infiltrative stage of lymph node tuberculosis. Employed locally with other measures, results are often hastened in tuberculosis of the small bones, superficial joints, and skin. The locally applied x-rays and general sunlight or lamp irradiations can be combined. When x-ray exposures are thus added to light therapy, the duration of treatment is at times shortened.

3 Active Extrapulmonary Tuberculosis with Active Pulmonary Tuberculosis Accompanied by Fever—Both pulmonary and extrapulmonary tuberculosis show subjective and objective evidence of active or progressive disease.

(a) Sunlight is the treatment of choice in tuberculosis of the bones and joints and in genito-urinary tuberculosis, sunlight of low intensity in the early morning and late afternoon hours being used. The solar and air exposures should be given very gradually.

(b) Artificial lights (mercury arc in quartz and carbon arc). The mercury quartz light is often preferred when pulmonary disease is exudative and febrile, because of its great deficiency in heat rays. Better results are then had in tuberculosis of the intestine, peritoneum, epididymis and lymph nodes. It is advis-

able to alternate mercury quartz irradiations with exposure to the outside air and diffuse daylight.

(c) X-rays should not be applied locally to an exudative or progressive form of tuberculosis. If not progressive, the same conditions exist as for 2 c.

With an acute progressive tuberculous laryngitis, light irradiations applied locally are inadvisable until the acuteness has subsided, but, if other measures have failed, light irradiations may be tried as a final treatment, if only for their possible analgesic effect. Combinations of local irradiations of light and general body exposures are always employed, if possible, according to the indications mentioned.

CONCLUSION

Benefits are undoubtedly obtained by patients suffering from tuberculosis of the bones, articulations, peritoneum, intestine, lymph nodes and larynx when the entire body is exposed to carefully graded doses of natural sunlight or to radiation emitted by certain artificial sources of light rays. The beneficial results of such irradiation are due not only to ultraviolet rays. The visible and infra-red rays, as well as the conditions of the atmosphere, play a certain part in the therapeutic effect.

In tuberculosis of the skin, lupus vulgaris alone can be said to respond specifically to light. Scrofuloderma and erythema induratum react favorably at times to general and local exposure, although not as constantly. Lupus erythematosus does not respond to and may be aggravated by light.

In tuberculosis of the bones and articulations, it is generally agreed that suitable, graded exposure to natural sunlight is most effective in aiding the healing accomplished by orthopedic and other measures. Exposure to artificial sources of radiation is valuable here as a second choice.

Pulmonary tuberculosis, per se, is not an indication for light therapy, stationary pleural tuberculosis has often been helped by this measure.

Genito-urinary tuberculosis deserves a trial of such treatment in combination with other measures. Local exposure to ultraviolet rays of circumscribed tuberculous lesions of the urinary bladder has been shown to yield favorable results, but the method requires special applying devices and, above all, skilful treatment of the bladder lesion.

Ocular tuberculosis and aural tuberculosis respond infrequently to light. Oral tuberculosis is most resistant.

Fistulas are often resistant to such treatment. Post-operative sinuses, in contrast, are most responsive.

Intestinal, peritoneal and lymph node tuberculosis especially indicate light therapy and often are rapidly responsive.

In tuberculosis, overdosage has produced harmful focal reactions. Here light may set up a focal reaction similar to that of tuberculin.

The erythemic reaction is an accurate indicator of skin tolerance. Hence a preliminary exposure of a small area to gauge the minimal perceptible erythema will avoid undue burns.

Surgical versus conservative treatment of bone and joint tuberculosis. With any form of tuberculosis, light is to be used merely as an adjuvant and should be combined with all other indicated forms of therapy. The mainstays of treatment still remain, such as rest, proper dietary, and hygienic outdoor life.

With bone and joint tuberculosis, orthopedic measures combined with light still play the major rôle.

Indications for surgical intervention may depend on many factors economic and social conditions, the age of the patient, the joint involved, their number and the stage and extent of the disease, involvement of other organs such as the lungs and kidneys, and complicating abscesses or sinuses. Joint tuberculosis is still a local manifestation of a constitutional disease. Surgical measures are therefore in turn to be recognized as adjuvant procedures to be followed by prolonged conservative therapy. Intervention by surgical fusion is always to be seriously considered in the presence of advanced joint destruction. Restoration of function may occur in the synovial form of joint tuberculosis, even in the presence of large effusions, but complete functional return of motion in a joint is doubtful when the bony parts have been destroyed to a marked degree.

Roentgen therapy of pulmonary tuberculosis has many restrictions and important contraindications. Its healing effect in certain forms of extrapulmonary tuberculosis has been definitely established, but the limitations must be recognized, dosage carefully regulated, and treatments given only by experts in the field.

470 Park Avenue

LEPEL ULTRA-SHORT WAVE MACHINE ACCEPTABLE

Manufacturer: Lepel High Frequency Laboratories, Inc., New York

The manufacturer recommends this machine for medical and surgical diathermy. The unit is of the spark gap type. The wavelength is approximately 95 meters, although there is a second resonance point which generates a wavelength a few meters longer. The spark gap and transformer are kept cool by means of an electric fan, which operates while the unit is turned on.

Fig. 1—Lepel Ultra Short Wave Machine

Temperature measurements were taken on a spark gap and the transformer to determine whether they overheated. The temperature rises, after the machine had been operated on a full load for one hour, did not exceed the upper limits adopted by the Council. It is well fitted in a substantial cabinet and appears to be well made. The shipping weight is about 150 pounds.

The tissue heating ability of the unit was investigated in a clinic acceptable to the Council. According to a technic recommended by the manufacturer, cuff electrodes 25 cm wide and 50 cm long were applied to the human thigh, one near the hip

Fig. 2—Schematic diagram of circuit

and the other just above the knee. Felt and toweling about 25 cm thick separated the skin from the cuffs.

Thermocouples were inserted directly into the tissues. All thermometric devices were checked against a standard mercury thermometer. Thermocouples were in place during treatment. After twenty minutes treatment, the machine being operated at

the patient's tolerance, the temperature rise (average of eight tests) was observed to be more than that for conventional diathermy—the criterion for evaluating short wave machines which the Council has adopted.

Burns may be produced by this machine, but, with ordinary care, they may be avoided, their likelihood to occur is much less than with conventional diathermy.

In view of the foregoing report, the Council on Physical Therapy voted to include the Lepel Ultra Short Wave Machine in its list of accepted apparatus.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

DIPHTHERIA ANTITOXIN—For description see the U S Pharmacopeia and Useful Drugs

Lederle Laboratories, Inc., Pearl River, N Y

Diphtheria Antitoxin Globulin Lederle Modified—This preparation differs from diphtheria antitoxin U S P chiefly in the method of refinement. The process of refinement is based essentially on a controlled method of selective digestion of the proteins of the immune horse blood with pepsin. As a result of this process as much as 90 per cent of the coagulable protein may be digested; a smaller portion is precipitated, and the remainder, a pseudoglobulin fraction is purified first by ordinary filtration and then by ultrafiltration and dialysis. Diphtheria antitoxin, globulin Lederle-modified is marketed in single syringe packages representing 1 000, 5 000, 10 000, 20 000 and 40 000 units of diphtheria antitoxin respectively.

RABIES VACCINE (See New and Nonofficial Remedies, 1935, p 380)

Lederle Laboratories, Inc., Pearl River, N Y

Rabies Vaccine Lederle (Semple Method)—(See New and Nonofficial Remedies, 1935, p 382)—Also marketed in packages of fourteen vials each containing 2 cc

TETANUS ANTITOXIN—For description see the U S Pharmacopeia and Useful Drugs

Lederle Laboratories, Inc., Pearl River, N Y

Tetanus Antitoxin, Globulin Lederle Modified—This preparation differs from tetanus antitoxin U S P chiefly in the method of refinement. The process of refinement is based essentially on a controlled method of selective digestion of the proteins of the immune horse blood with pepsin. As a result of this process as much as 90 per cent of the coagulable protein may be digested; a smaller portion is precipitated, and the remainder, a pseudoglobulin fraction is purified first by ordinary filtration and then by ultrafiltration and dialysis. Tetanus antitoxin, globulin Lederle-modified is marketed in packages of one vial containing 1,500 units of tetanus antitoxin in single syringe packages representing 1,500, 3,000, 5 000, 10 000, 20 000 and 40 000 units of tetanus antitoxin, respectively, and in packages of one cylinder containing 10 000 units of tetanus antitoxin for intraspinal administration.

NOVOCAIN (See New and Nonofficial Remedies, 1935, p 63, and THE JOURNAL, June 22, 1935, p 2256)

The following dosage forms have been accepted

Ampules Solution Novocain 2 per cent 3 cc Novocain 0.06 Gm. in distilled water to make 3 cc

Ampules Novocain Solution 10 per cent 2 cc (For Spinal Anesthesia) Novocain 0.2 Gm. in distilled water to make 2 cc.

WHITE'S COD LIVER OIL CONCENTRATE (LIQUID) (See THE JOURNAL, Sept 21, 1935, p 966)

The following dosage form has been accepted

White's Cod Liver Oil Concentrate Liquid Vials 5 cc—Each two-thirds minim (0.038 Gm.) has a vitamin A potency of not less than 2 280 units (U S P \ Revised 1934) and a vitamin D potency of not less than 320 units (U S P \ Revised 1934)

MERCUROCHROME (See New and Nonofficial Remedies, 1935, p 309)

The following dosage form has been accepted

Surgical Solution of Mercurochrome—Mercurochrome 2 per cent dissolved in a vehicle consisting of 55 parts of 95 per cent alcohol U S P, 10 parts of acetone-U S P, and 35 parts of water, to which has been added sodium carbonate in the proportion of 0.1 per cent

METAPHEN (See New and Nonofficial Remedies, 1935, p 314)

The following dosage form has been accepted

Saf T Top Tincture Metaphen Tincture of metaphen 1 200 marketed in ampules having a capillary opening containing 2 cc and 15 cc.

RAYMOND HERTWIG Secretary

ACCEPTANCE WITHDRAWN

LISTER'S DIETETIC FLOUR (SELF RISING)

Manufacturer—Lister Bros, Inc, New York

Description—Self-rising mix, containing casein, sodium caseinate, ground ivory or palm nut (*Phytalephas macrocarpa*), sodium bicarbonate and calcium acid phosphate

Manufacture—The casein curd is precipitated from milk with hydrochloric acid. The curd is worked and washed with water at least five times, dried and ground. The sodium caseinate is prepared by adding four parts of sodium bicarbonate to the curd (described above) from 100 pounds of milk. The mass is dried on hot rolls.

Definite proportions of the formula ingredients are automatically mixed and packed in cartons

Analysis (submitted by manufacturer) —

| | per cent |

Claims of Manufacturer—Recommended for diets low in carbohydrates

Uselessness as a Special Purpose Food—Lister's Dietetic Flour, manufactured specially for use in diets restricted in dextrose formers, was accepted in November 1933, before the Committee adopted definite requirements for a special purpose flour of this character. To be eligible for acceptance at this time, such type of flour shall contain dextrose formers yielding dextrose in an amount not greater than 3.3 Gm per hundred cubic centimeters (the dextrose equivalence being computed as the carbohydrate, plus 58 per cent of the protein, plus 10 per cent of the fat content of the food). Dextrose formers of Lister's Dietetic Flour, on the other hand yield 13 Gm of dextrose per hundred cubic centimeters (based on submitted information that 100 cc of the product weighs 39 Gm).

There is authoritative evidence that commercially prepared special diabetic foods such as this flour are of limited usefulness to the diabetic patient and that the availability of insulin makes them no longer necessary. Artificial substitutes for ordinary foods are not to be favored, it is much better for the diabetic patient to learn how to plan his diet with foods in common use and readily available. The diet should be exactly prescribed in carbohydrate, protein and fat, and total calories.

The designation of a food as a diabetic food merely because it is low in carbohydrates is now unwarranted and misleading and gives the erroneous impression either that the food taken in unrestricted quantities in diabetes is harmless or that it has remedial action. Except for the necessity of restricting foods to avoid overstepping the food tolerance there are no special diabetic nutritional requirements. The exploitation of starch-free or low carbohydrate foods containing an excess of protein for use by diabetic patients is unwarranted. Protein may be tolerated almost as poorly, if not quite as poorly as starch in diabetes.

Because Lister's Dietetic Flour is adjudged without usefulness or special adaptability for inclusion in diets restricted in dextrose formers, it no longer will be listed among the accepted foods of the Committee on Foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

RUGER'S PURINA BRAND WHEAT BREAD

Manufacturer—John B. Ruger Sons Company, La Fayette, Ind.

Description—A whole wheat and white flour bread made by the sponge dough method (method described in THE JOURNAL, March 5 1932, p 817), prepared from whole wheat flour, water, white flour, sweetened condensed skim milk, leaf lard, yeast, salt sugar partially defatted soy bean flour (omitted in summer) and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

HIDEX

Manufacturer—Scientific Sugars Company, Indianapolis, subsidiary of Union Starch & Refining Company.

Description—Essentially a powdered mixture of dextrans (64 per cent) and maltose (32 per cent), obtained from diastatic conversion of corn starch.

Manufacture—A mixture of formula proportions of ground corn (hulls and germ removed), water and diastatic barley malt is held at the proper temperature until the starch is converted into dextrans and maltose in the ratio of approximately 64 to 32 respectively. The resulting mash is filtered, the filtrate is heated to 85 C, admixed with charcoal, filtered, concentrated in vacuum, heated to 95 C, drum-dried in vacuum, ground and packaged.

Analysis —

| | per cent |
|----------------------------|----------|
| Moisture | 3.0 |
| Total solids | 97.0 |
| Ash | 0.5 |
| Fat (ether extract) | 0.0 |
| Protein (N \times 6.25) | 0.5 |
| Reducing sugars as maltose | 32.0 |
| Crude fiber | 0.0 |
| Dextrans (by difference) | 64.0 |

Calories — 3.9 per gram 111 per ounce

Claims of Manufacturer—A high dextrin carbohydrate food for supplementing milk in infant feeding. Of especial advantage in diarrhea and postoperative feeding in that the dextrans do not readily ferment. Relatively slowly digested, the dextrose produced is only gradually made available for absorption.

JENNY LEE BRAND LONG MACARONI
JENNY LEE BRAND LONG SPAGHETTI
JENNY LEE BRAND ELBOW MACARONI
JENNY LEE BRAND ELBOW SPAGHETTI
JENNY LEE BRAND MACARONI SHELLS

Manufacturer—Minnesota Macaroni Company, St Paul

Description—Macaroni of various shapes prepared from durum semolina.

Manufacture—Same as for Minnesota Brand macaroni products (THE JOURNAL, Aug 3, 1935, p 369).

GRISDALE BRAND TOMATO JUICE

Distributor—Gristede Bros., Inc., New York

Manufacturer—P. J. Ritter Company, Philadelphia

Description—Canned tomato juice, retaining in high degree the natural minerals and vitamins. Seasoned with salt. The same as Ritter Tomato Juice (THE JOURNAL, Oct. 6, 1934, p 1069).

CLINICAL ASPECTS OF AVITAMINOSIS A

The relatively recent and eagerly awaited development of knowledge of the chemistry of vitamins has been preceded and paralleled by the compilation of information concerning the physiologic importance of the substances so designated. It is now evident that a number of descriptions of disease appearing in the early medical literature are largely manifestations of avitaminosis. Fundamental discoveries in the organic chemical, the physiologic chemical and the physiology laboratories have explained in many instances the rationale of certain historic dietary therapeutic measures. Although the major portion of the biologic results have been obtained with experimental animals, this information has gradually led to a recognition of conditions in the clinic which simulate those produced in the laboratory.

The fat-soluble factor, vitamin A, has not yet been isolated in pure form but has interested clinicians since early times through the manifestations of its deficiency. Accumulating medical literature testifies to the manifold functions in which this vitamin is involved. Avitaminosis A has been described as the cause of xerophthalmia, as an alleged etiologic factor in the formation of urinary calculi, as being of significance in creating a resistance to infections in the respiratory organs, as related to keratomalacia and other pathologic lesions of the cutaneous system, and as a necessary dietary constituent for prevention of lesions of the nervous system. The skin changes of chronic avitaminosis A are particularly striking, many varieties of dermatitis may be seen before xerophthalmia makes its appearance. Mackay¹ recently made a critical review of the clinical literature and concluded that the earliest effects of vitamin A deficiency could probably be detected in the skin. This author undertook a large scale test on infants to determine the effects of prophylactic treatment with vitamin A. The results² taken

as a whole indicate a perceptible increase in the resistance to minor infections of the skin in those infants given the extra vitamin A. Mackay concludes that, although only a fraction of the minor skin infections seen in the infants studied by her could be attributed solely to a lack of vitamin A, there is in avitaminosis A a generally lowered resistance in these cases. She believes that infants fed on dried milk should have their dietary supplemented with vitamin A as a routine measure.

The relationship of keratomalacia to vitamin A deficiency was demonstrated conclusively by Bloch,³ who was one of the first to stress the fact that the disease is characterized by general manifestations of which the ocular symptoms are only a part. Despite the fact that a considerable amount of literature has appeared on this aspect of avitaminosis A, the reports have dealt primarily with experimental problems and with reports of ophthalmologists. Clinical and pathologic studies have been few and there has been little effort to correlate the general symptomatology and the pathology. A good beginning toward satisfying the need for this type of data has been made in the excellent clinical and anatomic study of avitaminosis A among the Chinese⁴ reported from Peiping Union Medical College. The investigators have studied the records of 203 patients suffering from various manifestations of avitaminosis A and the material obtained from seventeen necropsies and twenty-two biopsies. The results are discussed from the points of view of etiology, pathology, symptomatology, physical examination and diagnosis, and an attempt is made to correlate the clinical and pathologic pictures. Sweet and K'ang find that diet is, of course, the factor of prime importance in the causation of the deficiency disease of keratomalacia. Other factors are related to incomplete utilization of the ingested vitamin sources. The pathologic studies are of particular interest because there have been few thorough investigations of the pathology of avitaminosis A in man. In the necropsies performed by Sweet and K'ang, lesions of the eye were most frequent, changes in the respiratory tract ranked next in frequency. The pathologic appearances are described in good detail, as are the symptomatology and the observations in the physical examinations. The authors also present the diagnosis and treatment of the cases under their observation and finally offer cogent comment designed to correlate the results. Case histories of the seventeen patients who provided the material for the necropsies add to the value of their contribution. This most complete investigation offers a model for further reports, wherever possible, of this type.
